Tim B. Robinson writes:

Is fred back yet? I have some unexpected csyn output and I was wondering if he had installed his latest version before going away. The main thing I'm worried about is it seems to be complaining about the xbmux2 cells having e qualifiers on the selects. I seem to remember we decided in the reviews something had to change there, but appears we may have a disconnect.

Fred will be back next Monday, 6 Mar.

I have some Csyn results which I ran last Monday in Fred's directory:

```
~/chip.bsrc/euterpe/verilog/bsrc/tbr_euterpe-pass1.csyn
```

this file is about 1.3Meg (I believe yours result was bigger?) and is based on some code/csyn tables which which is probably still testing and has not released. I have not had a chance to look at these results. Maybe we could go over them together sometime today? Or you could point me to the suspicious results in the file...

Hi bp,

If you're interested the results from the BOM 240.0 testcase that I ran
can be found in

~fwo/chip.bsrc/euterpe/verilog/bsrc/tbr_euterpe-pass1.csyn

Fred will be back next Monday, 6 Mar.

I have some CSyn results which I ran last Monday in Fred's directory:

~/chip.bsrc/euterpe/verilog/bsrc/tbr_euterpe-pass1.csyn

this file is about 1.3Meg (I believe yours result was bigger?) and is based on some code/csyn tables which which is probably still testing and has not released. I have not had a chance to look at these results. Maybe we could go over them together sometime today? Or you could point me to the suspicious results in the file...

It shows the same real errors and also reports the 2 i/p mux problem:

Reason: Two e inputs. Use diff. instead
exclusive inputs

instance path: top.xnbdbufdout47 .nb_dbuf_xsela0_ab1peh_1
cellname path: top.eam2ffdh16s11x2a.sel_a1peh_1
instance path: top.xnbdbufdout47 .nb_dbuf_xsela0_ab1peh_0
cellname path: top.eam2ffdh16s11x2a.sel_a1peh_0

drivers

instance path: top.xnbdbufrselbuf1.nb_dbuf_xsela0_ab1peh_1
cellname path: top.ea1plqh3s4x2a.q_b1ph
instance path: top.xnbdbufrselbuf0.nb_dbuf_xsela0_ab1peh_0
cellname path: top.ea1plqh3s4x2a.q_b1ph

exclusive topmost nets

instance path: top.nb_dbuf_xsela0_ab1peh_1
cellname path: top.nb_dbuf_xsela0_ab1peh_1
instance path: top.nb_dbuf_xsela0_ab1peh_0
cellname path: top.nb_dbuf_xsela0_ab1peh_0

For some reason there is a lot less output associated with this.

The tlb problem is gone in fred's version.

The reported short in cc that I couldn't see is still reported but the bogus error message that I was seeing is gone.

To: 'guarino'; 'sandeep'; 'gmo'; 'jeffm'; 'wayne'
Cc: 'hestia'
Subject: Software Bringup Meeting Minutes - March 1, 1995

Software Bringup Meeting

March 1, 1995

Next Meeting: March 8 at 10:00 am.

Attendees: guarino, gmo, sandeep, jeffm, doi

New Action Items

Item: Build a longer sync-op test with nb activity.

Who: guarino

Status: New

Item: Build and run stress test (without printf's)

Who: guarino

Status: New

Item: Build test that accesses and runs in a bunch of memory spaces and states.

Who: doi

Status: New

Item: Can a single cylinder (in an exception 'loop') lock out other cylinders?

Who: jeffm

Status: New

Item: Determine what is initialized (and how) in terp

Who: guarino

Status: New

Review of Action Items

Item: Terp needs to model 'guaranteed forward progress for cache miss' in the same fashion as the hardware does.

Who: lisa

Status: In progress.

03/01 Lisa has contacted mws and is implementing the same scheme used by the hardware.

Item: Tests need to be written to verify performance issues

Who: lisar

Status: In progress.

02/22 We need to flag performance problems as errors.

Tests could be identified (and perhaps written) to measure and verify performance of the hardware for things like cache misses, tlb initialization, exceptions, etc.

03/01 Lisar has started writing these tests.

Item: Running Real-time Benchmark on Euterpe/Calliope HW Simulator
(combined with previous `Run real-time test on the HW simulator)

Who: gregg, lisar

Status: In Progress.

02/08 There are problems getting the benchmark to run on the software simulator. Work continues to find out where the problems are. The compilers, simulator, kernel, and benchmark areas are `frozen' (in terms of checking in new changes) until the problem has been identified.

02/15 It is estimated that by the middle of March we should have cycles available on the IKOS and a IKOS compatible calliope that can be run with the real-time benchmark.
Lisar will be the verification resource to help with running this application.

The benchmark is working and now the effort is focused on getting it to fit in the real-time and memory budgets.

03/01 The TV application has bogged down recently but work continues.

It is believed that this won't be ready to run (from the software hand the hardware perspective) until April.

Item: Specify and Design ISA/Cerberus Card

Who: gmo, lisar, dbulfer

Status: Pending

02/22 gmo, lisar, and dbulfer own the problem of specifying the design and assigning resources.

03/01 The specification meeting happened but design (hw and sw) has yet to begin.

Item: Determine what additional terp features are required
(formally `Status of Euterpe/Mnemo simulation')

Who: gmo, jeffm

Status: Pending.

02/08 Jeffm figured that in 2 - 3 weeks time there would be a need for terp/mnemo capability to support the verification effort.
An issue was raised that this may not be enough time for the required additions to terp to be made.

02/15 Gmo is to create a list of requested features for terp and then he and jeffm (and others?) are to review the list and determine what will be implemented by terp.

02/22 Gmo is ready to circulate the list.

03/01 Nothing new.

Item: Test interleaved access

Who: guarino, lisar

Status: Pending.

02/08 Loretta started to look at this but requires terp support.
Terp changes are on hold until the real-time benchmark is running again.

02/22 Test has been written (interleave) but has not been run on hwterp yet. Lisar is going to run this on the hardware simulator.

03/01 The test has been built, but not run yet. Derek is to check to be sure the hermes channels are enabled.

Item: Build microkernel tests for IKOS

Who: doi, sandeep, iimura

Status: In progress. Expected completion 2/15

- 02/08 Create images for boot test, snapshot images for microkernel tests.
- 02/15 doi is still working on modifying the makefiles to build the _1 and _2 versions of this.
iimura is creating a tool that modifies the ELF headers to have the proper real addresses (not just virtual) and gmo has modified mking to be able to understand the new headers.
- 02/22 lisar says there are still problems building this.
iimura is generating a code segment that will run in both rom and cerbrom that will properly initialize dram and then branch to the test (which is in dram).
- 03/01 Sandeep is going to add code to boot so it can figure out if the cerb node is zero or eight.
Derek is to start building the kernel tests so they may be loaded and run on the hw simulators.

Item: DVT boot
 Who: sandeep
 Status: In progress.

- 02/08 First step is to get nano-boot running on the HW simulator.
- 02/15 Sandeep has completed the boot code and now we need to build a dvt that can be loaded by the DVT boot (i.e. it is loaded into the top 8K of D and I buffer).
Jeffm commented that for most DVTs, they must be loaded at the beginning of D and I buffer and the beginning of ram.
We will have to come up with an alternative for loading DVTs.
Sandeep noted that dvts will not be started in event mode which is in contrast to jeffm's mail about the initial state for dvts (but we knew this already).
- 02/22 We want to understand if we can modify the DVTs so they do not require that they are loaded at the beginning of D&Ibuf and ram.
- 03/01 Sandeep is going to implement a DVT boot mechanism.

Suspended Items

Item: Unsnap code
 Who: sandeep, guarino
 Status: Suspended.

- 02/15 The issue of restarting the hardware from an IKOS dump was discussed and the need for an architectural snap/unsnap facility was questioned.
Since the meeting it has been re-discovered (jeffm wasn't there to remind us of an earlier decision) that we are planning on loading architectural state into an IKOS simulation and not from a total IKOS logic dump.
We also determined that when it came time to run some of the larger tests (real-time benchmark) we would need the capability to start an IKOS simulation from an architectural dump anyhow.
- 03/01 For the short term we are going to focus on a simpler approach for loading and running DVTs, the kernel, and kernel tests. This item will likely come back in April.

Item: Refine remote debugging environment
 Who: sandeep
 Status: Suspended

- 02/08 We have to decide how control (and state) is to be returned to the debug stub after a test runs.

02/15 Sandeep is not going to have time to start on this for a while.

Item: Create performance test plan

Who: jeffm, guarino

Status: [11/30] No progress as focus is on functionality.

We continue to run tests to help us compare terp vs hardware performance.

We still need to put together the actual performance tests that need to be run on the hardware.

Completed Items

Item: Current hardware traces should capture the `nb full' signal

Who: jeffm, lisar

Status: Done.

03/01 Jeff has introduced 4 new signals to some of the dump files (this will be propagated to others). There are two `nb full' signals, a gtlb hit, and the memory management enabled signals captured now.

Test Status and General Discussion

Jeffm reports that we have enjoyed significant test success recently.

Both jeffm and djc's sync tests pass. Jeffm is currently chasing bugs related to off-chip Ifetch.

It is estimated that test focus will shift to running boot and kernel tests during the week of March 7 - 13.

Lisar is spending time getting boot from cerberus working and simple performance tests running.

There was some discussion of how we could classify certain tests to determine if they were capable of being loaded by nanoboot (dvtnanoboot) or if they required boot.

bss.	nanoboot	- can load onchip test, onchip data, and onchip
can	boot	- in addition to the capabilities of nanoboot, it
		understand ELF files and preload dram.
		- boot currently takes the top 8K of I and D buffer
		(and may be moved to the top 4K if we need
space)		and as a result leaves 24K of I and D buffer
		available for the DVT.

Subject: Re: Global routing results

Kurt Wampler writes:

Well...I have a global routing result. Looks awfully dense in spots.
Of the 12,959 nets attempted, 174 failed to route completely in a M3/M4 linesearch pass. Among the global nets attempted, I count 95 busses of 10 or more bits which are still differential (just grepping for '_n<[0-9][0-9]').

I think it might be interesting to have a large-scale plot of this global routing. To that end, in:

/n/godzilla/s2/wampler/plot

I have converted the results to Compass format so they can be plotted.

Is there anything special I need to do to get the "gaudy" colors, or are those now the standard defaults for rplot?

Hmmm...

I _think_ to get the gaudy colors you need to give 1 additional argument to rplot:

-pdf /u/vanthof/compass/mobi/euterpe/plot/plot.pdf

is that correct, Dave?

Cc: 'euterpe'
Subject: Re: Cerberus Node Number available in Exception Status Register

My earlier elaboration didn't provide for desired security features of the Euterpe chip. In an earlier meeting I verbally describe a change, which may not have seen written form.

The rule should be:

if the node number is 0 or 1, boot from the flash ROM.
if the node number is 2-255, boot from Cerberus node 0.

The flash ROM needs to be accessable via Cerberus when node==0.
When node==1, Euterpe should be "secure," in that the contents of the flash ROM is not accessable via the Cerberus port.
For 2<=node<=255, it doesn't matter whether the flash ROM is accessable (it likely wouldn't be present anyway).

Additional security would result if other Cerberus registers are made unwritable except by Euterpe itself; this is a less direct method of potential attack, as all one can do via the Cerberus registers is set the analog levels in parts of Euterpe and Hermes to something marginal, and hope that some resulting undetected error causes a security violation. However, given the level of effort which has been used to thwart cable boxes in the past, making this impossible is probably worthwhile.

Subject: Cerberus Node Number available in Exception Status Register

My understanding is that bits 55..48 of the exception status register are going to contain the cerberus node number (presumably bits 63..56 are still zero).

Thus, in the current implementation, if this value is 0x08 (or if it is non-zero?) then we are booting from cerbrom, if this value is 0x00 then we are booting from rom.

Can you confirm this?

Thanks,
Derek

Subject: Recommended PC+PL to use for IKOS/Zycad

I can't find a single vector midpipe PC, but I think I found a better endpipe PC than the WP version you are using now.

It is the next-sequential PC (including that the job is completely released) and corresponds to the R19 stage of the pipe, becoming the R14 for the next job. By using it as R14, we get a PC before the branch updates itself with its target. The net name is:

euterpe/rg/rgpc/pcPlIncWR[63:0]

The driving flop instance names for bit 63 downto 0 are:

euterpe/rg/rgpc/UpcIncWP/Uinc{7,6,5,4,3,2,1}/Us/u{7,6,5,4,3,2,1,0}

euterpe/rg/rgpc/UpcIncWP/Uinc0/Us/u{5,4,3,2,1,0}

euterpe/rg/rgpc/UpcPlIncWR/u{1,0}

I can change the levellog program to match. Let me know.

If you are happy with this change, I can change the verilog wrap.log strobe statements to print the same PC to make verilog and ikos/zycad compare more readily. Or maybe I should do this 1st on verilog to prove it works, although then I would like a commitment that we would follow up on ikos/zycad.

What do you think? I think this would eliminate 1 source of confusion and speed debug.

thanx,

mark

Derek Iverson wrote (on Wed Mar 1):

My understanding is that bits 55..48 of the exception status register are going to contain the cerberus node number (presumably bits 63..56 are still zero).

That's the plan, but we haven't managed to find room to route the extra wires out of Cerberus yet . . .

Thus, in the current implementation, if this value is 0x08 (or if it is non-zero?) then we are booting from cerbrom, if this value is 0x00 then we are booting from rom.

Can you confirm this?

The current rev of Heastia only brings bit 3 of the Cerberus address to the expansion connector, so 0 and 8 are the only choices there. However, the Euterpe itself should boot from Cerberus whenever the address is non zero.

Subject: Cerberus Node Number available in Exception Status Register

Derek Iverson wrote (on Wed Mar 1):

My understanding is that bits 55..48 of the exception status register are going to contain the cerberus node number (presumably bits 63..56 are still zero).

That's the plan, but we haven't managed to find room to route the extra wires out of Cerberus yet . . .

Thus, in the current implementation, if this value is 0x08 (or if it is non-zero?) then we are booting from cerbrom, if this value is 0x00 then we are booting from rom.

Can you confirm this?

The current rev of Heastia only brings bit 3 of the Cerberus address to the expansion connector, so 0 and 8 are the only choices there. However, the Euterpe itself should boot from Cerberus whenever the address is non zero.

According to Craig's most recent posting, this behavior will have to change so 0 and 1 are equivalent for boot source selection.

Yes. I don't know how the last one went away, but it is related to
the facts that

1. Rich M released a new version
2. I did a release in proteus/ged which probably backed out his
release
3. My .checkoutrc failed for some reason which hopper was
investigating

Still doesn't explain what removed the old version.

I'll try getting it back now, meanwhile you can point the the snapshot
euterpe proteus.

Mark, did you discover what was the cause of that missing script.

Subject: euterpe metal drcs

The snapshot metal drc's are still clean. The only 'notch' failures left are 5 from the via twinning post processing phase. one of those is still the bizarre clock wire in front of the cr block.

The lowers are still running and should be done in a day or so.

so far so good.

Thanks,
Dave

Hi,

I am going to build another top-level tomorrow evening. Here is what we've decided in today's meeting :

1. swap rgxmit and hz. Improve uu placment for wires to rgxmit

Geert, Jay

2. cerberus wires at top-right of the die .

Tom Vo

3. look at i-cache strip, starting at ctioi

Hopper

4. GT and tlb wire assignment

Tbr

If dr is ready by tomorrow evening, I'll pick that up too.

lisa, could you provide more information when you have a problem?
unfortunately since we don't actually work with the software
packages that you use, or even understand what they do, there's
a lot of background that we lack. you tend to send very short
messages which often do not explain very well what the
problem is, or even include enough information to
be able to make a test. in this case i have no idea
where 'voyager' is, since it's not in your \$PATH.
i don't know what it is either, all i can surmise is that
it's an X app. but even then i'm stuck, since i have no
clue what RGP is or what sort of font vddQueryFontExtent
might want.

unfortunately it's a typical human tendency when given incomplete
or difficult to figure out messages to say to one's self "i don't
know what this is, i'll look at it later". so your requests
get dropped to the end of the queue, after the ones that i
have enough information to solve.

Sorry eric. I knew ken would know what to do as he fixed it for me a
couple of days ago. I'm not sure I understand exactly what it wrong as
I expected it to be fixed but it was related to a file
(bootp?) on the auspex not having the correct address of my hds (it
had the old address).
Ken then wrote a script addfont in my home directory which gives me a
temporary workaround.

Unfortunately we got a visitor this evening, so I've not had much time so far.

First I thought I'd build a gt locally then put a top level together with just that and the gtlb so I can see just the nets of interest.

gt iterated fine, but then I found myself having to hack at genpim2.pl and Makefile.tst etc to set this up with just the stuff i needed. On mnemo I have is set up so we can have multiple GARDS_SUBDIRS lists just like we have multiple exclude lists, and tom, alan and myself are now all able to do our own thing without stepping on each other. It's fairly easy to do. Should we retrofit this to euterpe?

Looking at the plot kurt made of the gt area it's very clear we have a really bad placement. One thing though is that the registers on the main output of the gtlb are placed right next to it (the output latches are unbuffered) and I'd like to swap them with the snake stuff because there are more wires going to that. Although this may introduce a little extra delay (thouth I think with a good placement the wires will be no longer on these outputs), I am thinking this is probably OK, since the gtlb was designed assuming 1.29GHz and so must have some slack. What do you think? It's expect to add 150u of M3 at most.

The GTLB is quite over-designed, so we should have some margin there.

My make does not run on ghidra any more . It keeps getting the path wrong .

Sample error message :
gmake: *** No rule to make target '/n/ghidra/N/ghidra/s4/vo/euterpe/verify/Makefile.rules'. Stop

The files are on ghidra s4 disk . I noticed that s4 is referenced differently now .
If I cd to /n/ghidra , s4 is now a link pointing to /N/ghidra/s4/ .

The make would run on machines other than ghidra however .

Any suggestion ?

I think the path came from another script , abspath , to figure out where I am

On ghidra , abspath gives :

/n/ghidra/N/ghidra/s4/vo/euterpe/verilog/bsrc

But on any other machine , the same command gives :

/n/ghidra/s4/vo/euterpe/verilog/bsrc

|the abspath in /a/muse/bin/ is broken.

|use the one in /usr/local/bin.

|BTW, it's silly to have N versions of the same thing.

|there's 2 abspaths, plus /usr/local/bin/pwd, all of

|which do the same thing.

Well, the /a/muse stuff is pretty old. We were keeping it around intentionally for historical reasons, since some of our snapshots contained explicit references to /a/muse/bin. Perhaps that's sufficiently ancient history that we can blow it away; I'm not sure.

/usr/local/bin/pwd is not a replacement for abspath. abspath takes an optional argument directory, and returns an absolute path to that directory. In the process, any .. in the given path is interpreted a bit specially: if there is a .parent symlink, the .. gets translated as what .parent points to; otherwise the normal interpretation is used.

I'm checking in what I have. i have put back the stuff that appeared to be truncated from your checkin.

My top level fails with:

```
gmake[2]: Leaving directory `/N/auspex/root/s15/tbr/euterpe/verilog/bsrc'
gmake CYCLETIME=926 gards/tbr_euterpe-iter.rload.lis
gmake[2]: Entering directory `/N/auspex/root/s15/tbr/euterpe/verilog/bsrc'
gmake[2]: *** No rule to make target `gars/tbr_euterpe-iter.rload.lis'. Stop.
gmake[2]: Leaving directory `/N/auspex/root/s15/tbr/euterpe/verilog/bsrc'
gmake[1]: *** [tbr_euterpe-iter] Error 1
rm tbr_euterpe.power.tab.local
gmake[1]: Leaving directory `/N/auspex/root/s15/tbr/euterpe/verilog/bsrc'
gmake: *** [tbr_euterpegards] Error 1
```

which is I assume because I do not have some sub-section stuff it's expecting now it's trying to do stuff for real.

The only thing I'm worried about is the power.tab stuff since that's different from mnemo. Please let me know if you think I broke anything.

Note, you will need to pick up genpim2.plat the same time.

It's a shell script that sorts a list of netnames by:

- 1) Subblock-internal nets (names contain a "/")
- 2) Global nets
- 3) Name
- 4) Bus bit (if found)

I was using it for my Euterpe routing experiments, and hopper checked it in while I was in the hospital. It can be invoked from /u/chip/tools/bin and he put the source in /u/chip/tools/src/gears. It would be OK to make a definition for it in Makefile.defs; it expects to have /u/chip/tools/bin in its path, but other than that doesn't need special environment.

I'm not sure I would have released it in its present form, but it's there now -- so I'll try to bring it up to standards if you see anything wrong with it.

Nothing wrong with it, it was just that I was cleaning up one of the euterpe Makefiles and I found it being invoked directly rather than through the usual definitions. Looks like we should add it to the standard Makefile.defs.

Subject: Main board PR's

Here is a list of Problem Reports that need to be taken care of, then closed before a Engineering Change Request (ECR) can be opened so we can begin work against the main board. I have cleaned up the PR's against this re-spin by providing a valid part number and assigning the a responsible engineer in the PCB category of gnats. If your name is in the first column you are responsible for seeing the PR through and having it closed. An ECR will be open in the next day or two against the main board. This is what Patty will be using as her check list of changes to be incorporated into the re-spin. The ECR requires that a PR be CLOSED in order for it to be added into the re-spin. If you have any questions or need a hand with gnat let me know and I'll drop by.

Thanks

Wayne

I was updating my euterpe baseplate with your latest stuff and I noticed an unreleased file in the clockbias section (clockbias.domains). Is this an oversight, or just something still in progress?

Tim

Follow Up Flag: Follow up
Flag Status: Red

I was rebuilding my local euterpe baseplate to pick up tom vo's latest stuff, and it failed in regenerating the clocks: sed -e 's/CBSOFA_MODEL/CBSOFA/g' basegen_tmp/cbsofa_model_base.pdl \
> cbsofa.pdl
/n/auspex/s15/tbr/euterpe/proteus/gards/basegen/derive_bounds \
cbsofa_model.ly /n/auspex/s15/tbr/euterpe/compass/visi.boe-all > cbsofa_bounds.gsub
/n/auspex/s15/tbr/euterpe/proteus/clockbias/gsub cbsofa_bounds.gsub \
< /n/auspex/s15/tbr/euterpe/proteus/clockbias/cbsofa.tdl.template > cbsofa.tdl
/bin/sh: cbsofa.tdl: Permission denied
gmake: *** [cbsofa.tdl] Error 1

Seems like we either need a chmod, or an rm before attempting to create this:

```
tbr@gamorra ~/euterpe/clockbias 420 % ls -ls cbsofa.tdl
3 -r--r--r-- 1 tbr      2358 Apr 26 1994 cbsofa.tdl
```

However, I have in the past rebuilt the clocks several times with no problem so do we understand what has changed to start causing this?

I'm looking at the euterpe module schematic, and it looks like all the instance names have gone from the main components. I think it is the case that you can call out instance names explicitly, rather than let GED make arbitrary PnP assignments (which change when you edit the schematic). This may be important when we convert to verilog and start building signal recording lists for simulation. We'd want the instance names fixed, and preferably recognisable.

Subject: Euterpe module Cerberus clock
Follow Up Flag: Follow up
Flag Status: Red

Should we be making provision on the Euterpe module PCB to be able to cut the trace, or include a zero ohm link which could be omitted, in the link between scout and sc? We would need this if we wanted to be able to reuse the euterpe module in a system which required a Cerberus clock from a different source for some reason. An example would be a system which needed two euterpe modules. While this is not an issue in Pandora itself, which will only have provision for one processor module, it may be relevant in some applications.

Subject: PCB layout schedule

Tim,

I wanted to revisit our conversation on the PCB layout schedule.

On Hestia Main, I added 2 weeks to do the Mnemo module in parallel to Howard laying out the Euterpe module. This really isn't a great significance in my learning if we are to be seperated. Revisit?

Need to set priority in the following:

Euterpe
Mnemo
Herminator - need for both Pandora and Hestia, Low?
Back Plane
PCI Bridge - higher than cronus or PCI Hermes
Cronus
PCI Hermes

Please clarify the priorities and I'll plug in the numbers.

Thanks
-Pattie

What you saw before was a 'path' property. I need to find out how to get real instance names on there.

Observing the date on this file, I see it's nearly a year old. It used to be created by doing a "cp -p" from a template file and then a "chmod 644". Since version 1.30 (11/8/1994) of clockbias/Makefile.rules this file is created by awk instead of cp and should always be owner-write by definition. All "cp -p" commands are long gone from this makefile, and the current version will never generate owner-readonly files unless the user corrupts his/her umask.

I see a number of obsolete files in /u/tbr/euterpe/clockbias dating back to Apr 26 1994, some of which are owner-readonly. I think it would be safest to blow away this directory in its entirety and start clean. Alternatively, a "chmod o+w *" would allow the make to proceed in the current directory context.

Hi Ken,

Mike Wageman's machine, euterpe, is not feeling very well. We tried to reboot it this morning, but the '/' filesystem is full and it won't come back up. I don't know how to get it into single user mode to try and clean up '/'. Can you help?

Thanks,
Dave

It can be released . There were a lot of GARDS activity when I checked in the file so I decided to delay the release . Of course , I promptly forgot about it .

I'll need to release the latest baseplate so I'll do both at the same time .

David told me that euterpe back up on the second reboot. However, I found the root disk was making a big noise. I have called AVCOM to order a disk to replace it before it crash. We will the disk in the next couple of days.

I think if we are specifying fields or busses they oughtta match.

It's only integers where I think we should infer the width.

It's safer that way.

Okay.

So...

if one side is a constant, then pad with 0's

if neither side is constant and the widths mismatch, then error out?

Yes, and error out if the constant is too big to fit in the field
width of the other side.

Right.

Subject: My Files on /n/ghidra/s2

Eric,
I'm having problems accessing my working files on
~billz/euterpe (this is a pointer to /n/ghidra/s2/euterpe).
I get messages such as:

n/ghidra/s2/euterpe: Operation would block.

or else hanging waiting for a prompt to return.
Ghidra is back up, right?

Any idea what's happening.
Thanks,
billz

PCOMP Version 7.1.21 of August 9, 1994

Processing Logic description: CLOCKBIAS
Processing Expansion level: SLNET

```
... Start of netlist processing.
... Circuit name: CLOCKBIAS
... Processing CDL.
... CHIPNAME:CBSOFA;

... Processing header of user PDL.
... PHYSICALLIB:PBUILD;
... Processing header of system PDL.
... PHYSICALLIB:PBUILD;
... Processing rest of user PDL.
... Processing rest of system PDL.
... Processing TDL.
... TECHNOLOGYLIB:CBSOFA;
... Computed Grid Size = 1000
... Final Processing.
... Successful physical compilation (with warnings).
>>> Loading logical netlist.
... Successful completion. GARDS design file created.
```

Tim,

euterpe module:

I checked in all of my Makefiles and stuff for pandora/p620_00014_0000/ged compile. I checked in 2 Makefile, Makefile.ged and Makefile.verilog, eventually these should be merge and some of the information put into morpheus/Makefile.rules/defs. I *did not* check in the morpheus/ged/custom/euterpe/chips_prt file that I hacked because we don't check those files in they are automatically generated. I did not release them because I have this hacked file to make it work.

The problem is that the chips_prt generator does not expect a body to have a bus at its interface. Rich McCauley says it can be done, but wants to answer the body vs gyg as source for the pin map. Rich's view is that the body file ought to be the source for pin map type of information. The gyg file can be the source for everything else.

To compile it check out pandora/p620_00014_0000/ged and morpheus. gmake morpheus and the copy my euterpe/chips_prt over the one automatically created. Then 'gmake' in pandora/p620_00014_0000/ged.

hestia main board:

The schematic is complete and checked in. I did check in my changes that the compiler was going to find.

I have not attempted to compile this, the only problem I would expect is that the calliope chips_prt is not correct.

I did check in a Makefile in hestia/p620_00001_0000/ged that is needed to setup the startup.concept, etc for browsing the schematic. I assumed you would want to do this.

This schematic needs to be reviewed. I did not verify that all of the gnats PRs have been taken care of though I do know that 2031 and 1777 should be done, they just need to be verified. I also know that noel has yet to spec new parts for the irout circuit. I put in the old one.

To Do for main board compile:

1. Decide what to do about chips_prt. I vote for sticking with the gyg because we already know how to deal with it.
2. Move all of the schematics to the new directory structure. If you attempt to browse the schematic, you will need to set up links to the hestia/ged dir (see my set up).
3. Put together the necessary Makefiles similar to the euterpe module.

4. Eventually all of the old stuff should be cvs rm'ed.

I have to go, but I think that should cover you.

good luck (see you monday),

jay

I think you have the right order here. However, the Herminator is not to connect between Pandora and Hestia, it's a placeholder for otherwise empty slots in the backplane. The PCI Hermes module is the link to Hestia.

Mark Hofmann wrote (on Tue Mar 7):

I haven't poked the code yet, but I think I recall seeing this.
What would you like Veqn to do with differing bit widths on either side of == ?

For example:

```
0 == foo[2:0] : 3 bits?  
bar[2:0] == 0 : 3 bits?  
bar[2:0] == foo[3:0] : Error ?
```

I think we should consider the last one an error. For the special case of one side being a constant it ought to get co-erced to the same size as the other side. If any non zero bits fall off the LHS, that probably ought to be an error too.

Okay. Mark said much the same.
I'm working on it.
I'll make a bit mismatch (where one side is not a constant) an error initially.
I can change this to a warning and bit extend one field or the other if needed.

I think if we are specifying fields or busses they oughtta match.
It's only integers where I think we should infer the width.
It's safer that way.

Okay.
So...
if one side is a constant, then pad with 0's
if neither side is constant and the widths mismatch, then error out?

Yes, and error out if the constant is too big to fit in the field
width of the other side.

I will fix the _V version, though it is not the highest on my list, since there is an _0
dump.

Software Bringup Meeting

March 8, 1995

Next Meeting: March 15 at 10:00 am.

Attendees: guarino, gmo, sandeep, jeffm, doi, gregg

New Action Items

-

Review of Action Items

Item: Build test that accesses and runs in a bunch of memory spaces and states.

Who: doi

Status: In progress.

03/08 The test currently runs out of ibuffer but accesses data out of dbuf, dram, and hermes devices. The support to build the tests that specify hermes data regions in in progress (mking).

Item: Can a single cylinder (in an exception 'loop') lock out other cylinders?

Who: jeffm

Status: Pending.

03/08 Jeff needs to talk with mws.

Item: Determine what is initialized (and how) in terp

Who: gmo

Status: Pending

0308 Gmo took this item.

Item: Terp needs to model 'guaranteed forward progress for cache miss' in the same fashion as the hardware does.

Who: lisa

Status: In progress.

03/01 Lisa has contacted mws and is implementing the same scheme used by the hardware.

03/08 Still in progress.

Item: Tests need to be written to verify performance issues

Who: lisar

Status: In progress.

02/22 We need to flag performance problems as errors.

Tests could be identified (and perhaps written) to measure

and verify performance of the hardware for things like cache misses, tlb initialization, exceptions, etc.

03/01 Lisar has started writing these tests.

03/08 Work continues.

Item: Running Real-time Benchmark on Euterpe/Calliope HW Simulator
(combined with previous 'Run real-time test on the HW simulator')

Who: gregg, lisar

Status: In Progress.

02/08 There are problems getting the benchmark to run on the software simulator. Work continues to find out where

the problems are. The compilers, simulator, kernel, and benchmark areas are 'frozen' (in terms of checking in new changes) until the problem has been identified.

02/15 It is estimated that by the middle of March we should have cycles available on the IKOS and a IKOS compatible calliope that can be run with the real-time benchmark.

Lisar will be the verification resource to help with running this application.

The benchmark is working and now the effort is focused on getting it to fit in the real-time and memory budgets.

03/01 The TV application has bogged down recently but work continues.

It is believed that this won't be ready to run (from the software hand the hardware perspective) until April.

03/08 lisar has starting building a IKOS compatible calliope.

The benchmark team is looking at a way to build a reduced subset of the test.

Item: Determine what additional terp features are required
(formally 'Status of Euterpe/Mnemo simulation')

Who: gmo, jeffm

Status: Pending.

02/08 Jeffm figured that in 2 - 3 weeks time there would be a need for terp/mnemo capability to support the verification effort. An issue was raised that this may not be enough time for the required additions to terp to be made.

02/15 Gmo is to create a list of requested features for terp and then he and jeffm (and others?) are to review the list and determine what will be implemented by terp.

02/22 Gmo is ready to circulate the list.

03/01 Nothing new.

03/08 Gmo has shown a group of people the list but will post it.

Item: Test interleaved access

Who: guarino, lisar

Status: Pending.

02/08 Loretta started to look at this but requires terp support. Terp changes are on hold until the real-time benchmark is running again.

02/22 Test has been written (interleave) but has not been run on hwterp yet. Lisar is going to run this on the hardware simulator.

03/01 The test has been built, but not run yet. Derek is to check to be sure the hermes channels are enabled.

03/08 Ready to run on HW.

Item: Build microkernel tests for IKOS

Who: doi, sandeep, iimura

Status: In progress. Expected completion 2/15

02/08 Create images for boot test, snapshot images for microkernel tests.

02/15 doi is still working on modifying the makefiles to build the _1 and _2 versions of this.
 iimura is creating a tool that modifies the ELF headers to have the proper real addresses (not just virtual) and gmo has modified mking to be able to understand the new headers.

02/22 lisar says there are still problems building this.
 iimura is generating a code segment that will run in both rom and cerbrom that will properly initialize dram and then branch to the test (which is in dram).

03/01 Sandeep is going to add code to boot so it can figure out if the cerb node is zero or eight.
 Derek is to start building the kernel tests so they may be loaded and run on the hw simulators.

03/08 Ready to be built for hardware.

Item: DVT boot
 Who: sandeep
 Status: In progress.

02/08 First step is to get nano-boot running on the HW simulator.

02/15 Sandeep has completed the boot code and now we need to build a dvt that can be loaded by the DVT boot (i.e. it is loaded into the top 8K of D and I buffer).
 Jeffm commented that for most DVTs, they must be loaded at the beginning of D and I buffer and the beginning of ram.
 We will have to come up with an alternative for loading DVTs.
 Sandeep noted that dvts will not be started in event mode which is in contrast to jeffm's mail about the initial state for dvts (but we knew this already).

02/22 We want to understand if we can modify the DVTs so they do not require that they are loaded at the beginning of D&Ibuf and ram.

03/01 Sandeep is going to implement a DVT boot mechanism.

03/08 Almost done. Testing and final check-in of changes soon.

Suspended Items

Item: Unsnap code
 Who: sandeep, guarino
 Status: Suspended.

02/15 The issue of restarting the hardware from an IKOS dump was discussed and the need for an architectural snap/unsnap facility was questioned.
 Since the meeting it has been re-discovered (jeffm wasn't there to remind us of an earlier decision) that we are planning on loading architectural state into an IKOS simulation and not from a total IKOS logic dump.
 We also determined that when it came time to run some of the larger tests (real-time benchmark) we would need the capability to start an IKOS simulation from an architectural dump anyhow.

03/01 For the short term we are going to focus on a simpler approach for loading and running DVTs, the kernel, and kernel tests. This item will likely come back in April.

Item: Refine remote debugging environment
 Who: sandeep
 Status: Suspended

02/08 We have to decide how control (and state) is to be returned

to the debug stub after a test runs.
02/15 Sandeep is not going to have time to start on this for a while.

Item: Create performance test plan
Who: jeffm, guarino
Status: [11/30] No progress as focus is on functionality.

We continue to run tests to help us compare terp vs hardware performance.
We still need to put together the actual performance tests that need to be run on the hardware.

Completed Items

Item: Build a longer sync-op test with nb activity.
Who: guarino
Status: Done.

Item: Build and run stress test (without printf's)
Who: guarino
Status: Done.

Item: Specify and Design ISA/Cerberus Card
Who: gmo, lisar, dbulfer
Status: Done (the specify part)

02/22 gmo, lisar, and dbulfer own the problem of specifying the design and assigning resources.
03/01 The specification meeting happened but design (hw and sw) has yet to begin.
03/08 Requirements posted. This is being removed from the list of items the software bringup group will track.

Test Status and General Discussion

Jeff talked about current HW and test status.

I missed most of the discussion printing off the proper version of last meetings minutes.

We got it covered! We have three configurations which support a 16
bit databus with choice of 1x16, 2x8, or 4x4 parts (16Mbit). Apart
from halved performance, everything would look the same as normal to
software. We also have three more configurations to do the same with
64Mbit generation parts when they become available.

We have tested it well stand alone, but have not covered any of these
configurations in system level tests. If you think it may be
important we need to increase the coverage at that level.

What is the scenario where we might want this?

What is the scenario where we might want this?

A cable modem based on Euterpe might need other than onchip memory.
Clearly, this could be slower than 100MHz, and it would be nice if it
could be found in increments smaller than 4MB. Given the poor
availability of 4Mb SDRAM, 2MB increments based on a single 16Mb chip
would probably be a good solution.

The channel disable was mistakenly inverted in an earlier checkin . We think that in the wrapchsim enviroment , where there's no hermes , nb got confused if the channel is enabled . The verilog simulator would come back with X-s very quicky .

The proteus build from scratch has completed. We have some changes to Makefiles to checkin and release.

Meanwhile, we should look at the result and see what we think. I need some suggestions or just plain looks at files by you folks to see if things are rational.

Lisar and I looked at some of the timing and cap files and saw some differences. They may not be relevant or as a result of newer models.

Were you comparing to the snapshot or to /u/chip. I had other evidence of something wrong in /u/chip which I forwarded to brinal to investigate.

We intend to start another build with the new makefiles from scratch before the weekend so feedback would be helpful before then.

tom, any suggestions of where to build a chip on the auspex which would end up being the mnemo snapshot.

Do you mean for the proteus, or the mnemo portion? For now I am using the euterpe snapshot for mnemo also. This will have to change as soon as we really freeze the euterpe version.

Subject: euterpe caches

Hi,

We are trying to free up some space on Euterpe and Mouss suggested to look into making the caches and tags smaller now that they onl have to run at 1.08 GHz and not 1.3 GHz.

Is there any possibility of reduing the sizes of the word-line drivers on the caches and tags and save us some area ? How much work would be involved ?

Thank's
Geert

We should bear in mind thought that we never really made it at 1.3GHz allowing for setup and hold times in the SOFA. We should also take account of knob setting 6.

Tim

Some tests like dramprintharder2_0, bgate_u, interrupt_u, gtlb_miss_u, and
barrel_u created a 10 or 15 tick nonblocking load use dependency on a
reg that had not been previously written non-X. The speculative load use
job, if a memory op itself, was then using its generated X address to get
an X LTLB miss. Separated isRsrdv from early part of problem pipe so that
load use hiccup could blindly kill the uncertain prblms. Fix is much broader
than the mem case to handle the 5 tick separation FXDPNT case (inspection).
uu/uuprblmr5.Veqn: Forgot that new NBLDUSE must be higher priority than
new LTLBMISS because the former indicates the latter may be X.
uu/uuprblmr8.Veqn: Inspection found ltlb miss was higher prio than BR!=Lva.
uu/uuprblmr11.Veqn: Inspection found incoming REPELFAIL treated as illegal.

Well I had just been typing vlit to find out if the license server was up ... and it kept saying it was down. This used to work for me.

However my make completed just fine .. this is what it used

```
INTERHDL_ELMHOST=rhea
INTERHDL_KEY_DIR=/n/rhodan/s3/euterpe/tools/vendor/ikos/vlit.2_5/vlitkeys /n/rhodan/s3/euterpe/tools/bin/vlit `cat
ikos_list` -scell_list -v -r0.05 -e -s vlit_cell_list
Checking out license...
Done.
```

Subject: GARDS problem ... URGENT

Hi,

I am trying to build at in the snapshot and it gets stuck at the first gplace (at-pass1). When I do a gardslic, it is there, but what I do a "top" on gamorra, I see :

```
13201 geert 1 0170508K 0K sleep 3:17 0.00% 0.00% <gplace>
```

I tried it earlier this morning on staypuft and I got the same result. I need this at before I can build a top-level. I think I'll need help to resolve this

The data is in the snapshot /n/auspex/s41/euterpe-snapshot/euterpe/verilog/bsrc/at

The makefile output is in bsrc/at/gards/makerrs

I think clio is having a problem that is causing your GPLACE job to hang.
I can't get fully logged in to clio to test things out, but your GPLACE
job is trying to put its window on clio and I think clio's catatonic
state is the source of the hangup.

As a workaround, why don't you kill the currently executing gmake & gplace
and override the display pointer to point to thoas:

gmake GARDS_DISPLAY=thoas:0 [other parameters]

If clio needs to be rebooted, I could get over to M.U. later this
afternoon and give it the boot.

Subject: instr_1.cie

Jeff

The tests instr and insn are not currently built by the default target.

I tried to build instr and got

```
lisar@nosferatu /s2/euterpe/stb/stand/diag 445 % gmake HWSIM=1 CHIPROOT=/n/nosferatu/s2/euterpe instr_1.cie
/n/nosferatu/s2/euterpe/tools/vendor/soft/stb/bin/tgcc -DDEBUG_LEVEL_1 -DNO_CALLIOPE -DSHORT -
MDupdate .depend -I../lib -g -O2 -c instr_main.c -o instr_main_1.o
/n/nosferatu/s2/euterpe/tools/vendor/soft/stb/bin/tgcc -xassembler-with-cpp -DDEBUG_LEVEL_1 -DNO_CALLIOPE -
DSHORT -MDupdate .depend -I../lib -g -O2 -c address.s -o address_1.o
```

address.s: Assembler messages:

```
address.s:94: Error: Unknown opcode: `aaddi'
address.s:97: Error: Unknown opcode: `aaddi'
address.s:109: Error: Unknown opcode: `aadd'
address.s:110: Error: Unknown opcode: `aadd'
address.s:121: Error: Unknown opcode: `aand'
address.s:122: Error: Unknown opcode: `aand'
address.s:131: Error: Unknown opcode: `aandn'
address.s:132: Error: Unknown opcode: `aandn'
address.s:141: Error: Unknown opcode: `anand'
address.s:142: Error: Unknown opcode: `anand'
address.s:151: Error: Unknown opcode: `anor'
address.s:152: Error: Unknown opcode: `anor'
```

etc

I suspect that this is why it was put in the cannot run yet category.

-- no
length limit. I used Geert's placement from Friday.

Disconnects after line search: 822 (1:39:25) CPU time (medusa)
Disconnects after maze: 159 (5:29:42) "
Disconnects after ripper: 40 (15:16:06) "

Results are in /n/godzilla/s2/wampler/euroute/geert_euterpe-iter.dff.

The ripper solved almost everything except the right corridor. It churned wires up there for many hours, ripping and rerouting, but just seemed to not have enough vertical resource to succeed. It might be possible to get those last 40 nets by hand, but it would probably take several hours.

I
didn't PGROUTE this design, so even if I did manually figure out a way to finish up the last 40 unroutes, it wouldn't be something we could export & LVS.

However...going back to the original assumption, it might be interesting to take wire lengths with estimated nitride non-airbridge capacitance coefficients out of this route and into simulation and see just what speed the chip would run at in this condition. I don't know how much work that would be on the simulation side, but it wouldn't take long to produce the capacitance numbers if the coefficients were known.

Kurt,

I think this is an interesting result. In fact, based on this result, and, as you mention, the possibility of the first chips from the fab using a nitride dielectric, I would say we are presented with (at least) 2 new choices: 1. Work on refining your route further to get rid of all disconnects and then see what the resulting speed is. 2. Explicitly turn down the clock to reduce cell size and congestion and then attempt a re-route. This second approach may, possibly, give us a faster chip than 1. if it results in fewer serpentine wires. I would say that both these experiments are worth pursuing further.

Comments?

-thanks,
hopper

Subject: Routing experiment

Hi,

I've completed a [perhaps interesting] routing experiment. Predicated on the idea that early wafers will be non-airbridge and nitride dielectric all the way to the top (i.e. M2 capacitance parasitic will be roughly the same as M3/M4), I ran a routing strategy that had full freedom in the M2 layer -- no length limit. I used Geert's placement from Friday.

Disconnects after line search: 822 (1:39:25) CPU time (medusa)
Disconnects after maze: 159 (5:29:42) "
Disconnects after ripper: 40 (15:16:06) "

Results are in /n/godzilla/s2/wampler/euroute/geert_euterpe-iter.dff.

The ripper solved almost everything except the right corridor. It churned wires up there for many hours, ripping and rerouting, but just seemed to not have enough vertical resource to succeed. It might be possible to get those last 40 nets by hand, but it would probably take several hours. I didn't PGROUTE this design, so even if I did manually figure out a way to finish up the last 40 unroutes, it wouldn't be something we could export & LVS.

However...going back to the original assumption, it might be interesting to take wire lengths with estimated nitride non-airbridge capacitance coefficients out of this route and into simulation and see just what speed the chip would run at in this condition. I don't know how much work that would be on the simulation side, but it wouldn't take long to produce the capacitance numbers if the coefficients were known.

Oops. Sorry. This is my fault. I accidentally killed the snapshot trying to terminate my leafgen release. Please restart yours and it should continue cleanly.

Brian

Hi Geert,

I noticed you've been working on the top-level route through the weekend.
How are things looking currently?

Jay Tomlinson wrote (on Tue Mar 7):

To Do for main board compile:

1. Decide what to do about chips_prt. I vote for sticking with the gyg because we already know how to deal with it.

We convinced rich staying with the gyg files was the best course, and dan has been implementing the chips_prt generator.

2. Move all of the schematics to the new directory structure. If you attempt to browse the schematic, you will need to set up links to the hestia/ged dir (see my set up).

Some additional issues have been raised by tbe and we should spend a few minutes thinking through what we really want.

3. Put together the necessary Makefiles similar to the euterpe module.

Dan has been concentrating on the euterpe module and was still having problems as of friday. He said he would have it all completed over the weekend.

4. Eventually all of the old stuff should be cvs rm'ed.

Yes.

Curtis Abbott wrote (on Thu Mar 9):

What is the scenario where we might want this?

A cable modem based on Euterpe might need other than onchip memory. Clearly, this could be slower than 100MHz, and it would be nice if it could be found in increments smaller than 4MB. Given the poor availability of 4Mb SDRAM, 2MB increments based on a single 16Mb chip would probably be a good solution.

Another consideration is that the SDRAM controller design is based on the assumption that there is a fairly large multiplier between the SOFA clock rate SDRAM clock rate. So, although we have a great deal of programmability in the timing, resolution becomes poor at low SOFA clock rates and we may lose significant performance in the SDRAM as a result.

..recompile leafgen!
..
..Any ideas why?
..
..Tim
..

We changed several makefiles. i don't think leafgen should have been
affected but my senior assistant, tau may have an opinion.

It was, and now the timing is re-running. Take a look at the log in
s23/euterpe-proteus-cp/makerrrs
```

It looks to me as if proteus/spice/misc/{oper_pt.h,header} were rebuilt because brianl just added a dependency of it on the spice models file.

Sent: Monday, March 13, 1995 1:07 AM
To: 'mws'; 'dickson'; 'veena'
Cc: 'doi'; 'jeffm'; 'billz'; 'woody'; 'tbr'
Subject: regdepend_r25547_0

I spent some time trying to re-create the gmshrl6 failure of regdepend_r25547_0, which if you recall failed on BOM 238 (not taking an exception when it should have) and running okay now. I did a getbom of 238 but getbom got me 238.12 which went to x because it contained the "pruned gates". I did a bit of groping around in cvs logs and with the help of tbr realised that the problem may be that the gates just weren't in BOM 238.

The results of the run were at:

```
33720 -rw-r--r-- 1 lisar 34495400 Feb 24 11:32 res/24295.8960/results/regdepend_r25547_0.or
```

Here are mws's comments at 4.30 pm that day:

revision 239.0

date: 1995/02/24 16:30:11 LT; author: woody; state: Exp; lines: +1 -1

Release Target: euterpe/verilog/bsrc

Added xlu trap conditions to uu that were removed from mc by dickson.

Now we (as in tbr et al) think that this exception gmshrl6 was at that point only added to the standalone datapath simulation environment not in the toplevel. Which would explain why the test didn't take the exception and runs now.

So, am I off the hook? Are we satisfied that the failure is understood?

Lisa R.

Jay Tomlinson wrote (on Tue Mar 7):

To Do for main board compile:

1. Decide what to do about chips_prt. I vote for sticking with the gyg because we already know how to deal with it.

We convinced rich staying with the gyg files was the best course, and dan has been implementing the chips_prt generator.

2. Move all of the schematics to the new directory structure. If you attempt to browse the schematic, you will need to set up links to the hestia/ged dir (see my set up).

Some additional issues have been raised by tbe and we should spend a few minutes thinking through what we really want.

3. Put together the necessary Makefiles similar to the euterpe module.

Dan has been concentrating on the euterpe module and was still having problems as of friday. He said he would have it all completed over the weekend.

4. Eventually all of the old stuff should be cvs rm'ed.

Yes.

I realized that some more changes for connectors in morpheus/verilog/slibsrc will need to be made. They will need to be converted from vector to scalar notation to match the schematic body. This is what needed to be done anyway since it allows gyg2v to create the verilog directly from the gyg. Note gyg2v doesn't currently support vectors.

Subject: connection timed out errors in snapshot build

Hi,

Tim said that you wanted to be advised of our "network/system" problems so that you could try to track things.

The latest snapshot proteus build failed because two (out of 836) mlobe simulations failed when the connection timed-out while trying to find/execute the hspice binary. Both time outs occurred on pelorus.

E.g.:

./mlor2dh2s.scr: /n/auspex6/s23/euterpe-proteus-cp/tools/vendor/hspice/standard/
bin/hspice: Connection timed out

Time of error:

Subject: IMMIDENT/FINAL DECISION: IQ cut from 7 to 4 quadlets; br pred impact

As explained below, we have essentially made a final decision to reduce the instruction queue from 7 quadlets to 4 quadlets.

Since the decision is already essentially final, no date for it to become final or effective is given.

We have always had a predicted branch&target alignment effect on ifetch performance that could affect loop performance. This effect was poorly advertised but only applicable to less than 1 of 16 random cases until recently. Of course, compilers or other tools might make the cases less than random for somewhat worse results.

The size of the instruction queue was decided back in the old days when the on chip ifetch rate was once every four cycles (one can look at it as ticks or major cycles for the same relative result).

7 quadlets of queuing was the minimum necessary to keep straight line code free of ifetch delays, and that size is what we still had until now. Predicted branches could mostly live with 7 and not see delays, but there were a few cases that would have required even more quadlets in the instruction queue to avoid delays.

We never claimed that predicted branch performance was perfect.

Recently it became clear that routing congestion near the ICache made it impossible to support so much instruction queueing.

The old instruction queue is now overkill when evaluated against the same criteria that originally justified it because the ifetch rate is now double what it was. The size justified by those criteria is 4 quadlets. This results in a new predicted branch performance rule once the excess quadlets are removed:

A correctly predicted branch that does not hold in issue will cause its target to suffer a 1 tick ifetch delay if the branch and target PC's have the same (quadlet) offset within their hexlets. If the branch holds in issue for any reason (e.g. eta restriction, pc behind) then this ifetch delay does not apply, and if the target instruction was not ready to issue anyway, then the ifetch delay will trade with the otherwise 1st cycle of issue delay for no net loss.

Examples of correctly predicted branches subject to pred ifetch delay:

from pc=0x200 to pc=0x180

from pc=0x408 to pc=0x228

Examples of correctly predicted branches NOT subject to pred ifetch delay:

from pc=0x200 to pc=0x184

from pc=0x408 to pc=0x22C

from pc=0x400 to pc=0x22C

from pc=0x30C to pc=0x178

from pc=any to a load/store/branch instruction

With the excess that we had before, the rule was the same except only applied when the branch and target were both the FIRST quadlet in their own aligned hexlets. I think if we only had the quarter rate ifetch as originally planned, the rule would have been similar to what we are ending up with now with half rate ifetch and a 4 quadlet instruction queue.

...if anyone wants to have a look at the disconnect pattern. I can make a small plot of it tomorrow. At first glance, it doesn't look much different from the plots we were examining this afternoon.

Okay. So this is simialr to, or slightly better than, the ordering we had been trying up to line search? (ca. 2900 disconnects?)

Does that say that ordering is not critical. Or do we need another point on the curve to be able to draw such an inference?

Subject: mnemo drc's finished

The mnemo upper drc's have finished and aside some notch errors in the metals from the router and via twinner, the metals are clean.

The lowers are basically clean EXCEPT for 5 big holes in the poly layer:

93560, 6000
93720, 6000
67680, 5520
69840, 5520
178560, 5520

The floating poly check died when it filled up the disk. Is it possible to have larger than 2GB partitions on sunos? We've reached the point where a single stage within a dracula run for mnemo exceeds the current file system sizes created for dracula jobs. These are currently about 1.6GB and it would be nice to have about 3GB per partition.

I'll manually fix and restart the floating poly check.

Thanks,
Dave

There has been some sort of update going on with ea cells. It looks
like the PDL is out of sync with the netlist. That could be because
the
update had not completed when you ran, or it could be because the
verilog library model is not out of sync with the layout

Tim

We've seen this for a day or so now.
Warren did these pin names change? I don't think so.
I'm not sure what's going on.
The chipg is currently empty, so there are no updates in progress.
We need to track this down.
Tom- are all PDLs up-to-date by your reckoning?

I wonder if this is a schematic vs. layout problem

I added a description of the DRAM overrun problem we expect to have when the clock ration is below 10. Could you reproduce the formula you had so we can specify the general case. ie, assuming we can select both dram an hermes clock ratios, what is the inequality that has to hold to guarantee it works in the worst case?

Thanks
Tim

OK. Done. I think. I hope "Ratio ≥ 10 " isn't too simplistic. I'm sure you'll let me know if the explanation is inadequate.

Regards,
billz

I tried again and it still fails. The .lst file has

#1 ERROR(47) Wrong description in libraries for part
PIN_NUMBER Syntax error: Number of sections in line 13
File name : '/n/auspex/s10/chip/morpheus/ged/custom/euterpe/chips_prt'

Is there still something that needs to be released to /u/chip?

There has been some sort of update going on with ea cells. It looks like the PDL is out of sync with the netlist. That could be because the update had not completed when you ran, or it could be because the verilog library model is not out of sync with the layout

Tim

This problem is due to the fact that dan has not yet released his new tool for generating chips_prt. I have a chips_prt in my dir that will work, but /u/chip/morpheus will generate the wrong thing. I should have remembered this earlier. Until this tool is released, I think you are stuck unless you want to check out and build morpheus/ged, morpheus/gyg, and morpheus/verilog. Although gyg does not build completely because of missing pcad .prt files. Is there any reason to keep this stuff? Minimally, I think we can remove the default rules that package the pcad parts.

I just released morpheus/slibsrc, but the chips_prt error will prevent you from getting that far.

My new gt placement has converged. Looks to be 300 atoms smaller, and it now fits between the spars, though it does use one more row. Before I release it I'd like to try my mini top level route just to make sure it looks OK too.

I do see a couple of anomalies which I think we need to understand. The router has put int some metal 2 nets which form trombones across the RH clock spar and back for no apparant reason. Kurt, can you take a look at this in ~tbr/euterpe/verilog/bsrc/gt/gards/gt-iter.dff?

I think it would be fine to disable the make of the pcad stuff.

I just released morpheus/slibsrc, but the chips_prt error will prevent you from getting that far.

Please send a note to dan asking him to release this stuff. I'd prefer to wait till I can do it without cheating.

>result late tomorrow morning.

Looks like the maze route ran pretty fast (about 4 hrs) -- indicating that
it runs a lot faster on short nets than on long ones. There are 850
disconnects after maze routing; not the kind of improvement we were
hoping for.

I think 850 is too large a number to feed to the rip-up router; it probably
disturbs (and degrades) at least 5 other wires for every unroutable that it
solves, so we really want to avoid using it at all if we can. 850
would also be a heroic number to solve by hand in REDIT.

The two dff's can be found in /n/godzilla/s2/wampler/inroute if you want
to poke around:

```
geert_euterpe-iter.dff.linesearch (3590 disconnects after linesearch)
geert_euterpe-iter.dff           ( 850 disconnects after maze)
```

The remaining unroutables are somewhat of a hodgepodge of short & long nets;
some of them are definitely busses that were part of our "early routing"
list.

These all look suspiciously like they were accomplished during the metal2 maze pass at the beginning of routing. It looks like the router is obeying the constraints we have given it. If we don't want the router to be able to thread wires through the clock spars, we could add some M2 obstructions on the left- and right-hand edges of each clock spar to prevent this. But if it's legal and it meets timing, why not permit it to do what it's doing? It uses no M3 or M4 resource to do this hookups and that's probably a win in terms of routing congestion.

These all look suspiciously like they were accomplished during the metal2 maze pass at the beginning of routing. It looks like the router is obeying the constraints we have given it. If we don't want the router to be able to thread wires through the clock spars, we could add some M2 obstructions on the left- and right-hand edges of each clock spar to prevent this. But if it's legal and it meets timing, why not permit it to do what it's doing? It uses no M3 or M4 resource to do this hookups and that's probably a win in terms of routing congestion.

I agree so long as we understand it and it makes timing it's probably harmless. My main concern would be if these popped up later at the top level and the significant extra metal 2 then meant we needed to power up.

Yes, they have. The part numbers have been assigned to both a socket and plug.

My belief is that the plug will be mounted on the Euterpe module (because it is a right angle part). The part number is :

370-00041-0000 CONN PWR PLUG RGT ANGL PANDORA

looks like it is still ticking but all too slow. seems to be ticking but chip is taking 47% of the cpu for spice simulations. all other machines are finished with leafmold. mercury has 20 layouts to go out of 309. maybe an improvement here might be to dynamically distribute the load to the machines. maybe give them 20 at a time and come back for more when you are done. later though. other machines have been finished for only 1-1.5 hours so maybe not too bad.

```

Subject: Re: PCOMP fails, why?

Yes, I have initiated pin name changes to help fix a lot of csyn errors on euterpe. However, I also have not been able to get a build of fwo_euterpe-pass1.splvs in bsrc since then. There seems to be some Makefile problem. It's always been something over the last few days.

The verilog models got updated on March 10th. See files in /u/chip/proteus/verilog/elib/eamem*v. I sent Tim some email after that happened requesting that he include these updated verilog files into to the snapshot. Maybe the timing files need to be included with the snapshot too, if they are done.

Fred.

Geert & I saw this problem on seperate builds (his euterpe , my mnemo) .
We did the same thing you're doing . I'll have to rebuild mnemo with that same recipe and
save the files for your inspection .
I'll do that later tonight .

Sent: Wednesday, March 15, 1995 3:32 PM
To: 'lisar'
Cc: 'tbr'; 'doi'
Subject: euterpe_wrap

In the checked in version of euterpe_wrap hermes interfaces are logged as:

```
$fstrobe (mninlog, "%b %x\n", clkIn0, din0);  
$fstrobe (mnoutlog, "%b %x\n", clkout0, dout0);
```

This needs file format needs to be munged to run through mnparsc.pl. I would like to change the fstrobe commands to:

```
$fstrobe (mninlog, "%x", din0);  
$fstrobe (mnoutlog, "%x", dout0);
```

This still needs to be modified because mnparsc doesn't handle x's in early on, iorate/hc put out '00' for 2 cycles (I suspect this is due to CHEATRESET). But this modification is just stripping off the 1st 30 or so lines.

Is there some reason that the above format was chosen? Is there a different tool that takes this other format? Is this the '-s' option (.sen format) to mnparsc.pl?

Subject: Software Bringup Meeting Minutes - March 15, 1995

Software Bringup Meeting

March 15, 1995

Next Meeting: March 22 at 10:00 am.

Attendees: guarino, gmo, sandeep, jeffm, doi, gregg

New Action Items

-

Item: Presentations on boot, gdb support, ukernel, ...

Who: sandeep

Status: New.

Review of Action Items

Item: Build tests that access and run in a bunch of memory spaces and states.

Who: doi

Status: In progress.

- 03/08 The test currently runs out of ibuffer but accesses data out of dbuf, dram, and hermes devices. The support to build the tests that specify hermes data regions in in progress (mkimg).
03/18 Support for hermes (including interleave) have been added. Still working on support for execution out of different regions.

Item: Can a single cylinder (in an exception `loop') lock out other cylinders?

Who: jeffm

Status: Pending.

03/08 Jeff needs to talk with mws.

03/18 No progress.

Item: Terp needs to model `guaranteed forward progress for cache miss' in the same fashion as the hardware does.

Who: lisa

Status: In progress.

03/01 Lisa has contacted mws and is implementing the same scheme used by the hardware.

03/08 Still in progress.

03/15 Progress continues.

Item: Tests need to be written to verify performance issues

Who: lisar, claseman

Status: In progress.

02/22 We need to flag performance problems as errors.
 Tests could be identified (and perhaps written) to measure
 and verify performance of the hardware for things like cache
 misses, tlb initialization, exceptions, etc.
 03/01 Lisar has started writing these tests.
 03/08 Work continues.
 03/15 Tim Claseman is assisting.

Item: Determine what additional terp features are required
 (formally 'Status of Euterpe/Mnemo simulation')

Who: gmo, jeffm
 Status: Pending.

02/08 Jeffm figured that in 2 - 3 weeks time there would be a need
 for terp/mnemo capability to support the verification effort.
 An issue was raised that this may not be enough time for the
 required additions to terp to be made.
 02/15 Gmo is to create a list of requested features for terp and
 then he and jeffm (and others?) are to review the list and
 determine what will be implemented by terp.
 02/22 Gmo is ready to circulate the list.
 03/01 Nothing new.
 03/08 Gmo has shown a group of people the list but will post it.
 03/15 Still pending.

Item: Test interleaved access

Who: guarino, lisar
 Status: Pending.

02/08 Loretta started to look at this but requires terp support.
 Terp changes are on hold until the real-time benchmark is
 is running again.
 02/22 Test has been written (interleave) but has not been run on
 hwterp yet. Lisar is going to run this on the hardware simulator.
 03/01 The test has been built, but not run yet. Derek is to check
 to be sure the hermes channels are enabled.
 03/08 Ready to run on HW.
 03/15 The tests generated by 'stgen' are also capable of testing
 interleaved accesses.

Item: Build microkernel tests for IKOS

Who: doi, sandeep
 Status: In progress.

02/08 Create images for boot test, snapshot images for microkernel
 tests.
 02/15 doi is still working on modifying the makefiles to build
 the _1 and _2 versions of this.
 iimura is creating a tool that modifies the ELF headers to
 have the proper real addresses (not just virtual) and gmo has
 modified mking to be able to understand the new headers.
 02/22 lisar says there are still problems building this.
 iimura is generating a code segment that will run in both
 rom and cerbrom that will properly initialize dram
 and then branch to the test (which is in dram).
 03/01 Sandeep is going to add code to boot so it can figure out
 if the cerb node is zero or eight.
 Derek is to start building the kernel tests so they may be
 loaded and run on the hw simulators.
 03/08 Ready to be built for hardware.
 03/15 Changes were made to libc and the microkernel (end-of-test
 support).
 Sandeep has also created a dummy_boot that will allow us to
 preload the microkernel to speed up simulation times. These

changes should be available today.

Suspended Items

Item: Unsnap code
Who: sandeep, guarino
Status: Suspended.

- 02/15 The issue of restarting the hardware from an IKOS dump was discussed and the need for an architectural snap/unsnap facility was questioned. Since the meeting it has been re-discovered (jeffm wasn't there to remind us of an earlier decision) that we are planning on loading architectural state into an IKOS simulation and not from a total IKOS logic dump. We also determined that when it came time to run some of the larger tests (real-time benchmark) we would need the capability to start an IKOS simulation from an architectural dump anyhow.
- 03/01 For the short term we are going to focus on a simpler approach for loading and running DVTs, the kernel, and kernel tests. This item will likely come back in April.

Item: Refine remote debugging environment
Who: sandeep
Status: Suspended

- 02/08 We have to decide how control (and state) is to be returned to the debug stub after a test runs.
- 02/15 Sandeep is not going to have time to start on this for a while.

Item: Create performance test plan
Who: jeffm, guarino
Status: [11/30] No progress as focus is on functionality.

We continue to run tests to help us compare terp vs hardware performance.
We still need to put together the actual performance tests that need to be run on the hardware.

Completed Items

Item: Determine what is initialized (and how) in terp
Who: gmo
Status: Done.

- 0308 Gmo took this item.

Item: Running Real-time Benchmark on Euterpe/Calliope HW Simulator (combined with previous 'Run real-time test on the HW simulator')
Who: gregg, lisar
Status: Removed. This has moved beyond the event horizon that we want to track in the software bringup meeting at this time. There is a separate 'benchmark' meeting that tracks detailed progress.

- 02/08 There are problems getting the benchmark to run on the software simulator. Work continues to find out where the problems are. The compilers, simulator, kernel, and benchmark areas are 'frozen' (in terms of checking in new changes) until the problem has been identified.

02/15 It is estimated that by the middle of March we should have cycles available on the IKOS and a IKOS compatible calliope that can be run with the real-time benchmark. lissar will be the verification resource to help with running this application. The benchmark is working and now the effort is focused on getting it to fit in the real-time and memory budgets.

03/01 The TV application has bogged down recently but work continues. It is believed that this won't be ready to run (from the software hand the hardware perspective) until April.

03/08 lissar has starting building a IKOS compatible calliope. The benchmark team is looking at a way to build a reduced subset of the test.

Item: DVT boot
 Who: sandeep
 Status: Done.

02/08 First step is to get nano-boot running on the HW simulator.

02/15 Sandeep has completed the boot code and now we need to build a dvt that can be loaded by the DVT boot (i.e. it is loaded into the top 8K of D and I buffer). Jeffm commented that for most DVTs, they must be loaded at the beginning of D and I buffer and the beginning of ram. We will have to come up with an alternative for loading DVTs. Sandeep noted that dvts will not be started in event mode which is in contrast to jeffm's mail about the initial state for dvts (but we knew this already).

02/22 We want to understand if we can modify the DVTs so they do not require that they are loaded at the beginning of D&Ibuf and ram.

03/01 Sandeep is going to implement a DVT boot mechanism.

03/08 Almost done. Testing and final check-in of changes soon.

Test Status and General Discussion

 -
 Jeff talked about current HW and test status.

The 'unix' test is causing the machine to reset on the hw simulator.

The dram controller occasionally gives the wrong quadlet and this has prevented a number of tests from running successfully.

There is a bug in the snake bus that causes X propagation during icache handling.

Gmo is running '_1' tests on terp and getting the print output.

Subject: euterpe simulation

I have attempted to add support for multiple dram configurations to the verilog simulation environment. This is because the _1 tests set the euterpe to use dram configuration 1 where as the _0 use configuration 0.
You will need to pick up a new Makefile and a new dr/dr.config.h and a euterpe_wrap.V.
Let me know if you have any problems.

Subject: Euterpe ready for DRC/SHORTS/LVS

Hi,

I build a euterpe in the snapshot for LVS and DRC. The snapshot is in /n/auspex/s41/euterpe-snapshot/euterpe.

This euterpe was build from the top directory (gmake euterpe), so that path should be pretty much working now.

This version contains all custom blocks and ck. As soon as Dave had grabbed the necessary files for DRC and LVS, I'd like to build a euterpe with everything in it.

Geert

I never noticed before that we don't have half swing cmos2ec1 converters. That is the cause of the above problem. I can add a buffer on 1 of the 5 bits. Of course, I have this old note asking whether there should be a synchronizer here anyway...

I never noticed before that we don't have half swing cmos2ecl converters. That is the cause of the above problem. I can add a buffer on 1 of the 5 bits. Of course, I have this old note asking whether there should be a synchronizer here anyway...

Since cmos to ECL converters only handle "DC" signals there is no power/performance advantage from having the half swing version.

Seems a shame to have to stuff a buffer in here. I have to admit I'm struggling to remember the reason for the "one must be half swing" rule here again.

Wasn't something about lower bipolar saturation if there was skew in the select switching such that all selects could look low (very low if full swing) for a short period?

My other question was on the synchronizer. Since we have become more conservative on synchronization, I wonder if changing page size without one could be too tricky. Maybe another way out would be to only enable IFe page boundry crossing checks if memory management is off (then we could say don't change page size with it on). If I have any cases where I was depending on a max page size to trigger hiccups to update ifetch pointers etc. (can't remember any at the moment although br prediction is ripe for such stuff), I could add that as a fixed separate case.

Probably. Seems moot in this case at least.

My other question was on the synchronizer. Since we have become more conservative on synchronization, I wonder if changing page size without one could be too tricky. Maybe another way out would be to only enable IFe page boundary crossing checks if memory management is off (then we could say don't change page size with it on). I don't have the document to hand. Where is the Cerberus field that controls this? If it's in octlet 6 it may be a problem since it would take immediate effect. If it's in a deferred octlet, we could demand a reset to change it.

I think the rationale for having no half-swing cmos2ec1 converters was that the only advantage of half-swing signals was their speed -- an irrelevant concern for signals coming from cmos.

Speaking of which... I guess I missed the reasoning for why (if I understand the error message) one of the exclusive inputs must come from a half-swing driver.

I thinks this will work:

Reset memory management off which IFe detects using the synchronized copy. Use that copy (not depending on Cerberus) to some forced page size (64 would make diagnostics happy by causing the existing high number of BHicMid's to continue). Software writes ifetch page size to octlet 6. No effect since IFe is still forcing, but allows cmos lines to settle. Software write memory management on to octlet 6. Sometime later this will cleanly switch from the forced page size to the settled page size. Software must not change both memory management and ifetch page size in same write. I presume no extra delay is needed between the writes as the hardware delays between the two should be enough for cmos to settle.

It would be easy to put some extra delay in the memory mgmt enable (say a couple of Cerberus clocks) to ensure te other lines are stable, then there would be no problem with a single write.

Also the page size was fully decoded in cerberus to save ecl atoms, but this costs 5 tracks through the choke point. We should encode to 3 wires and pay a few atoms in ecl.

Worth knowing if we are desperate.

Subject: notes on today's meeting

Following today's software strategy meeting, I volunteered to write up and distribute what I think we decided. I won't try to recapitulate the entire meeting, just the conclusions and the inconclusive parts.
Here goes...

First, I believe there was considerable clarification of various company goals. In general, we decided

- (1) it is important to continue work on Hestia, but to cast it as a technology demo, not a product;
- (2) it is possible to considerably simplify the software required for the earnback;
- (3) there is a way to think of Pandora as (almost completely) a modular package for our chips, as a channel to partnered and non-partnered customers, thereby mostly decoupling it from the earnback.

The emerging picture, then, is that we currently have 3 ongoing activities/goals, with one or more further activities/goals expected to emerge this year as a result of upfront customer commitments. One of the possibilities here is a cable modem, which we spent some time discussing and heard some breaking news about, but took no decisions on.

Thus, we were led to identify 3 questions:

1. What software is needed to achieve the earnback?
2. What software is needed to finish Hestia as a technology demo?
3. What software is needed to help sell Pandora-the-modular-package?

We spent some time interpreting the requirements for the earnback; we were in a "ruthless pruning" frame of mind. We decided it might be sufficient to sell production units of Euterpe (and Cronus) bricks, without even Mnemosyne. To run SPEC for the measurements, we could use our current OSF port, the /dev/host interface (which uses Cerberus) for i/o, and 16MB of memory. We would not necessarily ship Unix by 12/31/95. In that case, we would presumably ship a cross development environment so our customer(s) could do something with their bricks.

[Since the meeting, I've gone over Lois' summary of the contract with her. It's true that the language is remarkably unrestrictive in some ways. The key issues, I believe, will be (1) whether a brick is a workstation (no snickers, please); (2) whether the first spin of both Euterpe and Cronus will be robust and reliable enough to qualify as production units. The reliability issue appears to be mitigated by the fact that the contract essentially guarantees that any disputes as to the earnback are resolved in less than 6 months. The robustness issue is quite real, and sharpens the importance of making a good call on tapeout versus verification.]

We spent very little time talking about the second question -- I believe this is something the software managers should resolve internally and report within 10 days.

Our discussions of the third question were inconclusive. We identified 2 (related) end-user application areas for Pandora (SW development and combined SW/HW development), and 4 OEM application areas (video conferencing, video encoding, audio/video effects, internetworking). Of these, we felt that 1/2 or more could benefit from Unix, but some (video conferencing in particular) probably prefer something more like the microkernel. We discussed ways of using the other 4 threads with a single-threaded Unix port -- such an extension would be required, and a number of design ideas have been mooted.

Another part of this discussion was about shipping a cross development environment soon. This requires work on documentation, test, productizing in general, and perhaps some kind of DSP library. Also, having customers means supporting them, whether it's before or after hardware is available.

I suggest that the software managers, along with Tony, try to come up with a plan in this

area that we can present at a future meeting.

Actions:

- Tbr to verify we can put 16MB of SDRAM on a Euterpe brick.
- Gmo to verify we can run SPEC in 16MB (or alternatively, in 8MB, in which case Tbr is off the hook).
- software managers to clarify and write up Hestia tech demo goals.
- Tony and software managers develop and present plan on the Pandora software requirements questions.

Subject: Euterpe module

A potential requirement for 16MB of SDRAM in the Euterpe brick has come up.

This can be acheived using 8 4Mx4 parts which Euterpe supports, but the current PCB design does not. It may not be practical to have a single PCB layout support 2 1Mx16, 4 2Mx8, or 8 4Mx4 parts, but clearly we could have two different PCBs in that case. The most important thing is to be sure we have physical space to accommodate 8 SDRAM components and that we can cool them in the module.

Tom, pattie, can you look at these issues to make sure the current form factor can accommodate this option if it shoud become a hard requirement? The 4Mx4 part is in the same package as the 2Mx8.

The reasoning behind the half-swing requirement is simply that we have no way to guarantee that at least one of an "exclusive" set of bits is actually high. If a logical "don't care" case temporarily left all (full-swing) inputs low, we could run into electrical problems (such as saturating the bottom switch in a muxen gate) that would delay the gate's response once a select input rose again. A half-swing signal solves the problem by raising the "least positive voltage" to that of a vref (which is always assumed to be a "safe" input level).

In other words, we're confident that we don't have a *logic* problem. We should be correctly modeling all select inputs low as an indeterminate (X) output. The worry is that our timing models do not consider the transition delay between this state and a "normal" driven output.

I have started the lvs and a lower layer drc run. The upper drc is queued up to start after one of the mnemo jobs finishes. However, I don't normally 'save' the layouts, but will do so in this case.

Well, sort of.

Some of our multiplexer structures accept "mp" inputs at their top level and "np" at their second (or equivalently, "mp" on select inputs that get internally shifted down one Vbe). These gates have a somewhat different vulnerability: if the bases of the select transistor are all "low" 2pf signals then the emitters of the select transistors are low enough that the NMOS "current sources" will have severely reduced output current at certain operating conditions. This would make both outputs tend to float high.

We decided at the csyn/celltest meeting long ago that we were not prepared to invest the time required to verify that our timing numbers would be correct in cases like this. Even if the normal muxes work fine, we know that the muxens have a problem, and now we need a way to reliably differentiate between the two cases in csyn.

We could accomplish this by changing the signal naming convention to make the behavior explicit (I can see the rotten fruit flying my way from the folks who would have to change a bunch of pin names, then time and verify the resulting cells) or ask for a new csyn feature to let us apply certain rules only to certain cells (more rotten fruit, this time from fwo).

I don't know for certain, but from fwo's list it looks like it might be simpler to buffer a signal or two than to add the new csyn/signame "feature" this late in the game.

I don't know for certain, but from fwo's list it looks like it might be simpler to buffer a signal or two than to add the new csyn/signame "feature" this late in the game.

Agreed. In fact we had another debate earlier this evening about the importance of not making gratuitous changes because of the inevitable impact on the critical path.

Well, sort of.

Some of our multiplexer structures accept "mp" inputs at their top level
and "np" at their second (or equivalently, "mp" on select inputs that get
internally shifted down one Vbe). These gates have a somewhat different
vulnerability: if the bases of the select transistor are all "low" 2pf
signals then the emitters of the select transistors are low enough that
the NMOS "current sources" will have severely reduced output current at
certain operating conditions. This would make both outputs tend to float
high.

We decided at the csyn/celltest meeting long ago that we were not prepared
to invest the time required to verify that our timing numbers would be
correct in cases like this. Even if the normal muxes work fine, we know
that the muxens have a problem, and now we need a way to reliably differentiate
between the two cases in csyn.

We could accomplish this by changing the signal naming convention to make
the behavior explicit (I can see the rotten fruit flying my way from the
folks who would have to change a bunch of pin names, then time and verify
the resulting cells) or ask for a new csyn feature to let us apply
certain rules only to certain cells (more rotten fruit, this time from fwo).

I don't know for certain, but from fwo's list it looks like it might be simpler to buffer a signal or two than to add the new csyn/signame "feature" this late in the game.

Agreed. In fact we had another debate earlier this evening about the importance of not making gratuitous changes because of the inevitable impact on the critical path.

hopper,
Re: nb place and route

(for the purposes of this note, ignore my requests to get nb_mid a.k.a. nb_mid_new to "pack". For the moment, I just want the place and route run to complete through final so I can see if there are unroutable or timing errors)

OK, here's the problem:

nb-pass1 has no timing errors and (for the purposes of this discussion) and acceptable placement.

In pass2 pifpack moves one or more aligned cells from their original position on the extreme right-hand side. Then, there are two cells on the same row with the same alignment marker so pim2pif fails with a fatal error.

Both nb-pass1.pim and nb-pass2.pim consist of five sections, the last of which -- the custom data path on the right side -- begins with

```
.xoffset 1450
.yoffset 470
.nopifpack
```

... so how do I prevent the movement of the aligned cells on the right hand side? I thought the .nopifpack directive would do this.

The log file for this run is in ~billz/euterpe/verilog/bsrc/nb/nbgards.log with corresponding guards directory ~billz/euterpe/verilog/bsrc/nb/guards.

Thanks for listening,
billz

Thermally it shouldn't be a problem, since we will have force air to cool the SDRAMs in Pandora as compared to natural convection cooling in Hestia.

The difference between this condition and an acceptable 3 stack gate is less than 200mV. The NMOS sources if out of saturation will become like a resistor and hence does not behave like the BJT current sources, i.e. the reduction in current is not as severe as you may think. Furthermore, when the mux becomes active one of the sel inputs will be pulled high which brings the current source back to its "legal" level. Therefore, if we feel that this operating condition is unacceptable then we should question our normal operation also!

I don't believe that operation at the 'nominal' knob settings (i.e. rcd=6 and 400mV full swing) is the issue here. We were more concerned about electrical behavior at higher-swing settings where the difference in current source voltage would be much higher. There's not much drain-source voltage across the current source if the *highest* select input is a *low* 800mV full-swing 2p signal ($V_{cc} - 3V_{be} - 800mV$). (Yes B.P., one of those Vbe's will be at much lower current density due to both parallel connection and decreased current source current).

The point is *not* whether the gates respond properly once the condition ends.

The point *is* that we do not characterize the gates in this condition, and therefore we cannot assume that all structures with the "e" qualifier will function as expected. This was the decision that we took in the csyn/celltest meeting late last year. "E" signals inside custom structures are different, and we can easily modify the csyn rules to handle those cases.

I still think that it is simpler, if less elegant, to add a buffer cell to the *only* case in Euterpe where this restriction turned out to be an issue. It certainly seems a lot easier than proving to ourselves that there are no cases where we get into trouble and then convincing csyn to permit only it for only these cells.

I'd agree that one buffer is a small price to pay. An alternative that might even be a smaller price is to increase the fanin of the mux by one, and tie the extra select lead to vref.

Per discussion with Tim, and because Howard has adequate rough criteria for Pandora Euterpe pcb preliminary layout, and also because Pattie is ready to go on Hestia, I will complete the Hestia pcb criteria today and then proceed to the Euterpe design. Mark and I pinned Steve Brown down and he got the temp. keys extended for the pro/e to allegro interface (needed now for the Hestia layout) while a signature issue is resolved, so I am once more on the critical path. I anticipate we'll need Dan's help (tomorrow) once I've checked in the Hestia drawing, to help Pattie get it into Allegro.

Ugh. I was afraid that someone might mention the "vref" solution. This works electrically, but my understanding is that the Verilog logic model cannot handle vrefs as logically "useful" inputs. We ignore vrefs on OR gates, require that they be tied to the (ignored) _n pin on differential inputs, and don't get the nice feature that a vref tied to a mux select gives a "default" mux output (like the default case in a C switch statement).

So, it might work for this case, depending on what Verilog thinks is the logic level of vref. I suppose that it would work if Verilog thinks vref is logic 0, but not if logic 1, X, or Z. Again, it's a case that we've tried to avoid having to implement/verify, since it buys you nothing logically while only electrically guaranteeing a "least positive voltage".

Why do we need to run at 800mV? We are barely meeting speed at 400mV!
We used to design to 500mV and soon after that we had to reduce to 400mV to make speed and
size. If we have to run at 800mV the game is over.
Furthermore, the cells are also not characterized at that large swing.

Why add extra circuitry where we don't need. Why can't we put in smarts into the program
to indicate real problems and only fix those.?

If for some reason the only way we can make the first rev of euterpe run is at 800mV swing and 1/4 speed, this is far better than having it not run at all. Software types can use it for testing, investors and potential customers will be more willing to believe we have a chance of fixing it to work at speed, etc. Or perhaps we'll decide to do wafer sort testing at 800mV swing; I don't know.

Are we going to start characterizing the cells at the large swing?

I dunno about characterizing gates at all knob corners. The (partial) charter of this particular tool is to verify that we've connected things with appropriate signal levels such that the circuit should work over all knob settings -- at some speed. With any such tool, there are corner cases where we either have to add smarts to the tool, or change the design. The correct decision, obviously, is the one that costs less. We make this kind of tradeoff all the time with design rule checkers and every other mechanized verification process. In this case, adding one small buffer is a small cost; figuring out how to distinguish the OK cases from the bad cases, coding that into csyn, and probably munging a bunch of cells to put distinguishing qualifiers into pin names or whatever, seems a much higher cost.

Can the pin interface admit the possibility of using 8 2Mx8 parts for a 16 MB memory? This requires select pins and additional capacitance on the data pins, but would permit us to stock fewer SDRAM part types. It also presumes that 2Mx8 parts are no less available than 4Mx4 parts.

The fix is not in yet. Lisa Repka is still working on it. She has it essentially in and is in debug at this time.

- > Next I moved on to the dcache performance tests. I started getting
- > unexpected exceptions when doing dcache ops. I have looked at the hwterp
- > traces and can't see anything wrong with what is being attempted. It dies
- > on the second dcache access. I have sent an e-mail off to the simulator
- > folks.

The problem was mine. I had made some changes for the new tag spacing and when I made them the simulator still had the old spacing. Now that the simulator has been updated to the new spacing I just needed to update the conditional compile statements to reflect that.

I have done that and the test still passes on hwterp. I ran it on terp and have a trace printout. I have edited two files

~djc/sw/stb/stand/diag/memhi/cached.trace

~djc/sw/stb/stand/diag/memhi/uncached.trace

To include just the timing loops for the cached and uncached sections of the test. These show exactly the sequence of instructions and some guidance on how long each operation took on the simulator.

The next step is probably to analyze the terp trace files and see if anything obvious leaps out. If it doesn't then a more thorough analysis of the terp vs. HW simulator traces would seem in order.

Lisa has run the HW simulator on this same test. The results for both simulators are listed below:

hwterp : Uncached elapsed time - Cached elapsed time = 4840
HW Sim : Uncached elapsed time - Cached elapsed time = 3650

My preferences as far as operation is concerned 1. only have half swing inputs 2. allow full swing inputs, no reference 3. put in the reference

I don't think anything too disastrous happens with full swing inputs and no reference, but i'd like to avoid another set of operating conditions if possible. If we have to have another set of operating conditions, I think the hazards with a vref input are a bit higher than the hazards of getting the n current source out of the linear region. If it were a bipolar current source, i would be more concerned about getting out of the current source region.

If it is only a few gates, then the loss of adding extra stuff for half swing inputs ought to be minimal.. If it turns out its lots of gates then i would allow full swing inputs, no reference input.

Subject: Re: Fullswing selects; Csyn Euterpe BOM 247 errors

If people want to discuss characterization methodology as justified by general considerations, that is fine, but don't let the one csyn case here influence the discussion, because it is easy to fix and I am going to fix it.

The more helpful longer term improvement would be a mux that allowed its selects to all be off, or better yet random, and then still recover to valid operation in the next clock cycle. This would simplify certain control logic. But I know this is too hard on methodology and is probably very unportable across circuit/logic families. Thus I don't request it. Improvements less than that are unlikely to be worth their trouble, so I don't request them either.

Can the pin interface admit the possibility of using 8 2Mx8 parts for a 16 MB memory? This requires select pins and additional capacitance on the data pins, but would permit us to stock fewer SDRAM part types. It also presumes that 2Mx8 parts are no less available than 4Mx4 parts.

Subject: Planned 5pm disturbance.

In order to fix a number of exclusive input swing check csyn errors in Euterpe, we plan to change the sel_alpeh signal name in eam2ffdh16s11x2a cell to sel_alp2eh at 5pm today. This change will effect one schematic, one layout, and one verilog file:

- proteus/ged/ea/eam2ffdh16s11x2a/body.1.1
- proteus/ged/ea/eam2ffdh16s11x2a/spice.1.1
- proteus/ged/ea/eam2ffdh16s11x2a/spice_cn.1.1
- proteus/compass/layouts/eam2ffdh16s11x2a.ly
- proteus/exlax/elibsrc/eam2ff.V

Timing files for this cell should also be regenerated.
Let me know if we should delay this release.

Thanks,
Fred.

The difference between this condition and an acceptable 3 stack gate is less than 200mV. The NMOS sources if out of saturation will become like a resistor and hence does not behave like the BJT current sources, i.e. the reduction in current is not as severe as you may think. Furthermore, when the mux becomes active one of the sel inputs will be pulled high which brings the current source back to its "legal" level. Therefore, if we feel that this operating condition is unacceptable then we should question our normal operation also!

Isn't there also the consideration that for test, with no space transformer and poor power distribution we may have to turn the nominal swing to 900mV?

Of course in this case speed is not a primary concern.

The 900mv would presumably come with minimum current setting this minimizes the drop accross the current source. also i would assume at 900mv we could increase the power supply voltage if current source clamping is an issue

You run the risk of saturating the clock BJTs in the orlatch. This was the very problem we were trying to avoid in the mux latch. Since this is not a real operating condition it should just be something to watch out, we do not latch up the chip during the test.

I'd agree that one buffer is a small price to pay. An alternative that
might even be a smaller price is to increase the fanin of the mux by
one, and tie the extra select lead to vref.

Definitely not allowed by our current rules. The simulation model
won't handle it. We don't have a logic 1/2 to use for vref.

Ugh. I was afraid that someone might mention the "vref" solution. This works electrically, but my understanding is that the Verilog logic model cannot handle vrefs as logically "useful" inputs. We ignore vrefs on OR gates, require that they be tied to the (ignored) _n pin on differential inputs, and don't get the nice feature that a vref tied to a mux select gives a "default" mux output (like the default case in a C switch statement).

So, it might work for this case, depending on what Verilog thinks is the logic level of vref. I suppose that it would work if Verilog thinks vref is logic 0, but not if logic 1, X, or Z. Again, it's a case that we've tried to avoid having to implement/verify, since it buys you nothing logically while only electrically guaranteeing a "least positive voltage".

Back in the original mnemo days we did allow this. In that case we required that if used, the vref was always on the 0 select input. We then ignored that select input, and computed a replacement value as the nor of all the other select inputs. This had the effect that if no select inputs were asserted, the vref leg is chosen. However, that has the major disadvantage that if the vref option is not being used, we are actually ignoring the logic state of the 0 input.

It turned out that there were only two places in the design where we actually had the vref. On Euterpe, we decided to change the rules because the perceived advantage of being able to use the VREF was outweighed by the verification risk of not checking the 0th select input properly. In fact we have no static check that the one hot rule is obeyed, rather we have to rely on our verification vector coverage detecting a problem if we violate the rule. The model will produce X's if there are no selects asserted, or if there are multiple selects

asserted and the corresponding data inputs are not identical. This accurately reflects what the real circuit would do.

Why do we need to run at 800mV? We are barely meeting speed at 400mV!
We used to design to 500mV and soon after that we had to reduce to 400mV
to make speed and size. If we have to run at 800mV the game is over.
Furthermore, the cells are also not characterized at that large swing.

Only for test, where we know that voltage drops across the die will mean lower swings will
not give any noise margin.

Why add extra circuitry where we don't need. Why can't we put in smarts
into the program to indicate real problems and only fix those.?

I agree it's inelegant, but we ery trying to freeze the rules in order to get the job
completed. We have had a couple of changes in the last week, which while innocent on the
surface have cost us time because of the need to rebuild the snapshot for pin name

updates.

Can the pin interface admit the possibility of using 8 2Mx8 parts
for a 16 MB memory? This requires select pins and additional
capacitance on the data pins, but would permit us to stock
fewer SDRAM part types. It also presumes that 2Mx8 parts are
no less available than 4Mx4 parts.

We don't have the select lines. As far as availability goes, 2Mx8 is definitely the most
common, but I think 4Mx4 is a close second. 1Mx16 was single sourced in the first
generation, though most vendors are planning on introducing them in the second round.

From: paulb (Paul Berry)
Sent: Friday, March 17, 1995 4:58 PM
To: 'pandora'
Subject: Notes from mtg 95-3-10

[As usual, the fancy version is in /u/chip/pandora/notes]

March 10, 1995

Present: Tim Robinson, David Bulfer, Graham Mostyn, Lisa Robinson, Guillermo Loyola, Tom Eich, Geert Rosseel, Johnny Mudge.

Schedule

Gmo. The issue is when will hardware be available to the software developers:

How best to use software development time before hardware is available, how much time there will be after h/w is available.

PCB layout issues

Lisa is adjusting the schedule to take account of new estimates.

Verification

Lisa: There have been difficulties running configuration test in Verilog; they are extremely slow. Veena has been working on a method to load an advance configuration for the Verilog, and this may speed up the processing of tests on Verilog.

PCI testing has not progressed, mainly because the design is not yet complete; and testing will be done from the top level. Top-level simulation of the PCI is required because the tests assume the existence of the rest of the Mnemo functionality (so the tests can't reasonably be partitioned). Since the Verilog tester can't contact the Ikos, it will not be possible to run PCI tests unless there is a VHDL version of the PCI interface.

So PCI testing is basically waiting for completion of the Mnemo design.

Resources

needed for Mnemosyne compete with those needed for Euterpe.

Schedule

Tim. We had hoped to freeze Euterpe design by 3/15, but it no longer seems

possible to do so by that date. We should then review outstanding bugs and discuss compromises.

Lisa: Hardware tests are making good progress; 90% of the bugs found have been in the testing code rather than in the hardware.

Routing

Geert: Euterpe routing/timing decisions are progressing but not fast enough. Four weeks ago, the number of outstanding disconnects was 5,400; now it's down to 3,000, and are being completed at about 300 a week. Geert plus Richard Dixon and Bill Z are the only people available full-time for this work.

Euterpe is about ready for the final physical verification steps, Design Rule Checks (DRC) and Layout vs. Schematic (LVS).

Debugging metal

Lisa: What will we use for debugging metal? Since the process bring-up won't be done on Euterpe, can we commit to metal masks before metal bring-up? It might be necessary to

scrap masks that were made too much before process bring-up.

What is the vehicle for fab debug? Perhaps Orchis: it is comparatively simple (it's just a RAM, more customized than the other chips. Castor; Pollux; Calliope-0 might also serve. But under current rates of progress in design, Mnemosyne would still be first.

PCBs

Pandora PCBs. Tom: Still estimating 5/16. Have adopted larger but fewer fans, using a radial impeller. Should have heat sinks in about four weeks.

Two boards that have Mnemosyne modules

In addition to its use in Pandora as memory controller (where Mnemosyne is

mounted directly on the backplane), there are two configurations of Mnemosyne on an expansion card:

- o PCI-ISA Bridge
 - Used within Pandora
 - Connectors for:
 - PCI bus
 - ISA bus
 - Hermes channel (to the Pandora's onboard

Euterpe)

- The ISA interface on this card permits communication with an additional 5 cards on the Pandora's ISA bus

- The PCI interface on this card permits communication with an additional 3 cards on the Pandora's PCI bus

- o PCI-Hermes link for a PC

- Mounted on the PCI bus of a PC (or any machine with a PCI slot)
- Provides a link from the PC to the Hermes channel (presumably, to the Hermes port of a Hestia, or to a Pandora)

Heat dissipation

The heat sink for Mnemosyne on a PCI board is 4 inches square. Mounting in a PC imposes height and heat restrictions; we are assuming that the PC-mounted PCI-to-Hermes version can be restricted to 20 watts, and can rely on convective cooling (that is, without additional fans).

The version mounted within Pandora can have more RAM and can produce more heat.

Positioning of the SDRAM on the Euterpe module

It may be desirable to return to the original orientation. The position was turned to allow room for the analog processing in Hestia, but since that won't be included in the Pandora version, the original orientation may be retained.

Coordination of projects

Lisa: Can we revive regular schedule meetings with Mouss. There's an advantage to having regular reviews of schedule and status, and fore reviewing interdependencies. Graham: Yes, regular meetings desirable.

Impact of design changes on software.

Tim: The original plan was to bring up Unix on an X86 as a vehicle for developing device drivers, and then to bring up UNIX on Euterpe on a Hestia board, with the Cronus implementation of Hestia left until later. But now it seems that Euterpe is the gating item, so it will be possible to use the Euterpe module in Pandora rather than in Hestia.

Cronus design

To what extent should Cronus be designed with features that differ from Euterpe? The issue is that Euterpe assumed the existence of Mnemosyne and Calliope chips communicating via Hermes, but Cronus might have to operate in a context where none of those exist. Should Cronus then be modified to accommodate that different context? For example, at low clock rates, having Cronus retain the Euterpe design for I/O might not make sense. But one of the reasons for building Cronus was to demonstrate a portable design by implementing the same chip in more than one place and by more than one process.

David: We should change as little as possible. Many of the possible changes, while visible to Verification, would have no visible effect on software or software testing.

Gmo: Yes, but changes in I/O speed also affect memory access, and will affect benchmarks across the board.

If Cronus turns out to be the first chip available for testing, it certainly should have as few differences as possible from Euterpe.

Decision: The Cronus design should remain exactly the same as the Euterpe design.

----- A 3.3 V implementation would be preferable.

Cronus foundry

Geert: The plan to revive the cross-bar data-path (XDP) for Cronus has been abandoned.

There are two options for a Cronus process:

- o 5V at 400 MHz, for about 150 watts
- o 3.3 V at 200 MHz for about 30 watts

(These might imply different boards, different heat sinks) Perhaps we should do only the 3.3V version?

David: Either way, we have adequate power supply.

David thought VTI would be able to do a 3.3V version using a three-layer process.

This is true of course, and somehow the message I gave at the meeting, which was that the 4 x 4" heat sink would not need a local, heat sink mounted fan, but would have forced convection from the PCI area system fan, go garbled here.

This is an error in Paul's minutes. I think that the Mnemo module with DRAM is being confused with the Mnemo on a PCI card known as the PCI/Hestia card. Paul, can you correct the above to delete the reference to more RAM. The PCI/Hestia card will not have any DRAM (SIMMS) on it in any case. If this is unclear, please see me and we can publish the correction.

This is a new one to me! All the heat sink designs for Mn up to this point are for maximum power dissipation of 20 watts.

Please let me know if the power of Mn is expected to be higher than 20 watts.

We will have a good power number soon, but meanwhile 20W remains the target. I think the point that was being discussed at the meeting is that for the PC card we may well end up running the part more slowly at reduced power setting to drop the power well below the 20W.

I think it may be a generic exlax problem of some sort. I'm seeing similar trouble with mnemo. In that case there seem to be duplicate placements. I think alan understands what's going on in the mnemo case.

The problem seems to be in the datapath section of nb. The arrays and control section place, but the datapath does not .,

NB creates 5 *.pif files, 4 of them work at the top-level but the last one does not.

For who's interested : the 5 pif files are geert_euterpe-iter.pif.14 to 18. pif.18 is empty and that is the one that should contain the datapath part.

OK, it's not related to the mnemo probel, which alan has figure out (something out of date bacuase of a failed release).

Brian, what's the status of the snapshot rebuild? I'm working on mnemo, but am pointing to the euterpe snapshot proteus. I have a suspicion that this may be a new cell for which we may not yet have a layout at all.

The snapshot build died earlier this morning. I've released a fix and have restarted the getbom/.checkoutrc process on ghidra.

The layouts for these ea cells do exist in the snapshot, but the exlax/elibsrc/Makefile did not specify them at the time the snapshot pdls were last built. When the current build finishes, hopefully sometime late tonight, the pdls should be there. Until then, /u/chip should be consistent.

Tom,

Do you know what this would really look like?

Right now we have 4 surrounding the 2 in the center,
What would this look like? Basically another set? Where are
the connections coming from?

Can we mount a set of 4 on the other side? A piggy back board mount?

>From the sketches I've played with I don't see a fit, but the board
size has grown to 6X8 inches?
I'd like to get a better understanding of the dimensions and connections,
then I can better understand the issue.

Perhaps you can stop by Monday morning?

Thanks

Tom,

Do you know what this would really look like?

Right now we have 4 surrounding the 2 in the center,
What would this look like? Basically another set? Where are
the connections coming from?

Imagine how you have the 2 x8 parts straddling each of the 1Mx16
parts. In the configuration with 8 by 4 parts you would in effect
need to straddle each 2Mx8 with 2 1Mx4 parts.

As I mentioned in the earlier mail, it's probably not realistic
to make a single board that would support all 3 configurations,

or the main issue is how we would fit a total of 8 parts in there.

Can we mount a set of 4 on the other side? A piggy back board mount?

Mouss has suggested we put all the ram on a daughter card, so we can have different plug in modules. I don't like that idea because it adds complexity, and I don't think doing two euterpe boards for the 2 configurations would be any more work than doing 1 pluss a seletciotr of dsaughter cards.

>From the scketches I've played with I don't see a fit, but the board size has grown to 6X8 inches?
I'd like to get a better understanding of the dimensions and connections, then I can better understand the issue.

Perhaps you can stop by Monday morning?

As far as the connectivity goes, jay would be best equipped to discuss that.

Tim

Still from Euterpe, so I assumed it would just mean more SDRAMs above Euterpe.

Yes, the board is now larger, about 6" high by 7" wide.

What kind of daughterboard connector would we need in order to deal with the sub ns rise time memory signals? I actually think it is _more_ work, and more cost in manufacturing to have several daughtercards on top of the Euterpe pcb.

I agree. The only reason to do it would be to permit field upgradability. That's not an issue in pandora because we may well not even population the SDRAM since we have main memory on the Mnemo modules.

If the Euterpe brick gets used in a different system we can turn the board as necessary to provide the application specific options required.

I have a new version, 100% ahnd placed. I'm not sure if it's better. It took 7 iterations to converge and is a couple of hundred atoms nigger than the previous version.

However, it is very porus in M4 in the lower section, so it may well help. I'd like to do a bit more work on it before I give up.

If you want to take a look at it it's in
~tbr/euterpe/verilog/src/hc/hc0-iter.

It's still doing the capacitance simulations. Unfortunately, there was another reset yesterday. After I unstuck the getbom, it never started the .checkoutrc. When I checked later, all my processes were gone. Not knowing what happened or where it left off, I decided to be safe and start from another getbom.

There are about 100 more capacitance simulations. After that it should finish relatively quickly.

OK, not to worry, I have euterpe stuff to look at.

Hi,

The latest top-level route finished :

linesearch : 3000 disconnect
maze : 570 disconnect

Remember that this is the latest routing strategy, which routes the long nets first and results in more disconnects (but more localized)

- > Rich's section fully routes
- > GT still has considerable number of disconnects
- > There is a problem with the load data into the xlu that needs to be resolved with routing order. I will work on that.

- > at is off-set by 1 row compared to nb, sr and cc
- > still some disconnects in the datapath around rg

Top-level data is going to be in /n/ghidra/s3/geert/euterpe/verilog/bsrc/gards2 .

I will work on the nb-xlu routing problem. I think somebody should look at gt at the top-level.

Is this now with the version with single ended interconnect in the snake?

I have not checked in what I've been doing. The version I picked up from what I thought was the latest bom certainly looked all mincut, at least the data path was scattered all over.

- > at is off-set by 1 row compared to nb, sr and cc

Top-level data is going to be in /n/ghidra/s3/geert/euterpe/verilog/bsrc/gards2 .

I will work on the nb-xlu routing problem. I think somebody should look at gt at the top-level.

I'll take a look at it. I think there is still some scope to reduce horizontal routing by moving the address decoding part of the control to the left some.

Rich,

I have always run knobharder on the zycad where the model for dlatchq is the same for verilog.

I have done a run in verilog where I replaced the dlatchq model with the same model as is used on the Ikos. The test failed in a similar way to the stgen run.

The dump is on nosferatu /s5/euterpe/verilog/bsrc.

Subject: More on top-level euterpe

Hi,

There was a small problem with the route in the latest top-level. The early.net file was empty and therefore, no early nets were routed in this route. I fixed the problem and run it again. I believe that this will fix the xlu load data problem.

The lvs finished yesterday about 8:30 pm (took 3 days 2 hours to run).

There are mismatches:

NUMBER OF UN-MATCHED SCHEMATICS	DEVICES	=	4423
NUMBER OF UN-MATCHED LAYOUT	DEVICES	=	4204
NUMBER OF MATCHED SCHEMATICS	DEVICES	=	888836
NUMBER OF MATCHED LAYOUT	DEVICES	=	888836

There are NO shorts between labeled nodes, However, there still could be shorts between unlabeled nodes. I had hoped for a bit better result, but these mismatches could still be because it's not a fullchip.

I'll look at the output this morning.

Thanks,
Dave

I looked at dcacheeasy and traced evenModeUR X back through the preempt
logic to NB load data return on NBweDX1 X at 357690 to HC1prb[] at 356020
to dhchdis_abm[1:0] going from 3 to 0 at 355176 (I am guessing now
because I don't understand the microarchitecture in this area
and the dump only has euterpe and uu in it). The cpudin1[] bus into
HC1 is permanently X with the ivalid1 always active. The phil1_A2P
into iorate1 is permanently X. Maybe someone with more IO/HC
experience can take over now.

I will look at this and see if I can see anything from the information dumped.

Subject: euterpe lvs results

Hi,
The euterpe lvs results are a bit confusing, as it appears most of the bizarreness is from the schematics. The output of the lvs run is in:

```
/u/vanthof/compass/mobi/euterpe/tapeout/euterpe.compare/euterpe.lvs
```

There appears to be some confusion about vdde supplies in the schematics for the temperature sensor and the pll. Well, first glance at the output seems to indicate this. For the tsensa layouts, the signal VDDETS in the schematic seems to want to be VDDE, and in the pll, the VDDEP0 seems to want to be VDDE.

Is there some new power supply mapping that must go on?
I'll keep looking.

Dave

It looks to me like the problem is that hermes channel 1 is enable, but there
isn't a device there, because clkin1, din1 are both 'z'.

Yes, you are correct. I never did kill that run. Thank you for reminding me.

I'll start up another one this morning.

Would the missing ioquadcontrol also account for the bizareness with VDDEP0, VDDEP1, and VDDTS?

Thanks,
Dave

Do we have anything on this - Philip?

I left a data book on your desk with the page marked.
It's the same package as the 2Mx*8. The only difference is that 4 data lines are no connects on the x4.

From: paulb (Paul Berry)
Sent: Monday, March 20, 1995 8:31 PM
To: 'pandora'
Subject: Amended 3/10 notes on Mnemosyne heatsinks

Herman and Tom pointed out confusioin in the notes as sent.
What follows replaces the section that in the previous version was headed "PCBs" and "Two boards that have Mnemosyne modules"

Heat sinks for Mnemosyne modules

Tom: We have adopted larger but fewer fans, using a radial impeller. We should have heat sinks in about four weeks for all but the Mnemosyne used in the PCI-mounted PCI-Hermes link.

Three flavors of Mnemosyne modules

Aside to clarify the discussion: Mnemosynes turn up in three different roles that are relevant to Pandora:

- o Pandora's memory controller
Custom plug-in module:
 - connected to the Hermes channel on the backplane
 - 4 SIMM sockets (with 16 Mbit DRAM up to 128 MB)
- o Pandora's PCI-ISA Bridge module
Connections to:
 - Hermes channel on the backplane
 - PCI bus on the backplane
Permits 4 additional cards to be connected to the PCI bus.
 - ISA bus on the backplane
Permits 5 additional cards to be connected to the ISA bus.
- o PCI-Hermes link
 - In a PC, or in a Pandora, on the PCI bus
 - Standard long PCI card,
 - Provides a link from the PCI bus (of the PC or Pandora) to an external Hermes channel (for example, to the Hermes port of a Hestia or the Hermes port of another Pandora)

Heat dissipation for Mnemosyne within a PC

The heat sink for the Mnemosyne PCI-Hermes link (that is, for the Mnemosyne which may be located within a PC) is very large. (At the meeting, Tom estimated 4 inches square, but later said it will be larger.)

Mounting the PCI-Hermes link inside a PC imposes height and heat restrictions; for this card, we are assuming that the Mnemosyne will generate at most 20 watts (perhaps less, if its clock is set slower). It will rely on natural convection cooling, without additional fans.

Heat dissipation for Mnemosyne within Pandora

The memory controller (because of its additional RAM) and the ISA bridge module (because of its ISA and PCI controllers) will have greater power dissipation than the PCI-Hermes link (which will have only a few small components in addition to its Mnemosyne). However, in Pandora, the PCI-Hermes link will have the benefit of forced convection cooling from a system-level fan.

Requirements for the heat sink for the PCI-Hermes links have not yet been fixed.

Subject: March 20 Benchmark Meeting

We discussed 3 benchmark programs, digital TV, analog TV, and User Interface Demo. For the time being we will treat these as 3 independent applications; they make fine technologies demonstrations independently, and we avoid a number of systems issues. Eventually, we will consider the additional work involved in combining them.

For this discussion, we also assumed that we have working Hestia hardware. At next week's meeting, we'll discuss contingencies plans for using HW as it is likely to become available, in stages.

*'d tasks are not needed for the demos, and will be deferred.

Global dependencies (tasks needed by all
----- applications)

cache reorganization tool (Scott, compiler
person)
DLWS real-time (Tom, Scott)
Cerberus/Calliope support (khp, gmo)
Full bootstrap of Euterpe and Calliope (gmo,
khp)

Digital TV

Who: Gregg, Scott, khp, Tom, Doug, qua, ukernel
person (Gmo)

Remaining tasks:

System level encoder, to produce test data
streams
audio resampler integration
QAM integration
video resampling: test and integration
DLWS real-time
time and space budgets
cache reorganization
* 3/2 pulldown
* video resampling (e.g. CIF -> CCIR)
* closed caption
* AC-3
* changing channels (NIT information, keypad
support)

Analog TV

Who: Ron, khp, Tom, integration/ukernel person

Remaining tasks:

For RF decoding:
NTSC decoder test
BTSC audio decode (mono)
DLWS infrastructure
time and space budgets
cache reorganization

For baseband:
calliope fixup (DC coupling)

User Interface Demo

Who: Larry, Tom, integration/ukernel person

Remaining tasks:

input support (single task)
*resource compiler
TV Guide On Screen (fixed frame background)
DLWS: complete terp support, transparency,
alpha blending, spans, filters to avoid
sharp transitions

Combined Application

Tasks:

input support (multiple tasks)
flash file system
overlays

Doduc runs with the OSF simulator's default memory setting.

For the uninitiated, how much is that?

Subject: Euterpe Module

Hi Dan.

I know your working away on Hestia Main. Do you have an idea on when the Euterpe Module will be ready for layout?

I know its basicly the same as a portion of the main board with the exception of 2 connectors and I'd like to schedule this with some level of accuracy. If we have the Main board Tuesday, could we have the module by Thursday?

Just need to clarify the situation.

Thanks
-Pattie

I talked to dan earlier this evening, and he said the main board would finally be completed in the morning. I requested that he make getting the euterpe board higher priority than completing the automation. Given it's almost a subset of hestia, I would hope we can get it out very quickly after the main board is finalized, and certainly before thursday.

(Dan, let me know if there are any new hurdles!)

Subject: pcb layout schedule

Hi David!

I'm trying to get a realistic picture of the PCB layout schedule.
Hope you can put me back in check.

The Hestia-Main board was supposed to be in progress but the placement is hopefully being saved now.

The Euterpe module was supposed to start on 3-9 along with Mnemo. I'm hoping we have Euterpe by the end of the week and I understand Mnemo has a setback.

Can you help with schematic due dates for the following list of boards?

BOARDS Current Schedule (obviously wrong!)

MNEMO	3-9
Herminator	3-24
Back Plane	4-5
PCI Bridge	4-17
Cronus	4-26
PCI Hermes	5-17

Thanks
-Pattie

Woody should be able to handle mnemo as soon as we have the last
problems ironed out with Hestia. I had him lower the priority
relative to work on the Euterpe chip since we did not have the path
working. Assuming we have Hestia error free tomorrow, when's the
soonest you need it to avoid being held up?

Can you help with schematic due dates for the following list of boards?

I am re-running the mainboard through the packaging/eco process this morning to get some final reference designators picked-up. So the board should be available before lunch!

I don't foresee any hurdles with the euterpe net but will let you know asap if any come up...

Subject: Re: pcb layout schedule

I don't have an answer for you today. We can make progress on the simple things, like Euterpe, Mnemo-DRAM, and the Herminator. I cannot do the design work for the system (backplane, Mnemo-PCI bridge, Mnemo-Hermes, etc.) until i get my head out of the Mnemo chip design. That will not occur until mid-April. (Alan and I are attempting to get basic, crude chip sim up by the end of the month. It will likely be a couple more weeks, before the verification interrupts taper off.)

In summary, I will work on some real dates for you. I don't have them now. Working with Jay, we could probably come up with Euterpe, Mnemo-DRAM, and Herminator designs in a few days from the day he starts.

David

Cc: 'billz'
Subject: unpriv access to global virtual address

I'm developing x86 emulation software that in order to access memory, needs a 48-bit address space. Bit 47's special meaning confounds the problem, and my current plan is to use bits 63..48 and 31..0 for x86 segment and offset. The current cut-down LTLB only let's be use bits 63..48 when at priviledge level 2 & 3, which makes protecting other tasks from the emulation task difficult. I'd like to get the emulation task to run at priviledge level 0, native software to run at priviledge level 1, emulation system software at level 2.

This requires giving priv level 0 the ability to "bypass" the LTLB. A general capability for controlling this might involve 4 control bits (or perhaps 3, given that priv level 3 should always permit "bypass"), one for each priv level, controlling ltlb bypass for all threads (we don't need individual control per thread).

Do we have the prospect of inserting such control into the Euterpe design?

We're up and running on both Hestia-Main and Pandora-Euterpe.

I've been trying to run some edits here at home (about 200 parts to place and simple setups of the design constraints/DRC's) and its really painfull. The Allegro system has many pop-up forms that require redraws when they are complete or cancelled. I don't see this as a usefull situation for even weekends or evenings.

Frank had mentioned I might need the ISDN line for graphics and I have to agree. The 28.8 modem has been useful for about everything else including editing symbol/part data but falls short when editing full database "stuff".

What do you think?

You should try it on the set up in the machine room. Frank can arrange that. If it would be productive we should go ahead with the ISDN (assuming it's available in your area).

Frank,

Can you please set this test up? Let me know when your ready.

Thanks

Subject: output of euterpe/verilog/bsrc/au/.checkoutrc

The output from euterpe/verilog/bsrc/au/.checkoutrc is 224k, so it is not included in this mail message. Instead, check the file

/n/tmp/chiplog/geert.staypuft.6303.euterpe-verilog-bsrc-au

(which is accessible from all machines). This file will disappear in about 5 days.

By the way, the exit status returned by .checkoutrc was 0.

Tom,
We are thinking about making probe cards and D.U.T. boards etc. for euterpe. Where can we find the layout and pad list that will match what we are sending to the mask shop?

I believe (hopefully geert or vo will correct me if I'm wrong) you can find the best info under /u/chip/snapshots/euterpe (the new /u/chip/snapshots directory now has symlinks to all our snapshot disks, so we don't have to keep hunting in /n/auspex/s???). The layout should be accessible with a vlsi.boo file based on compass/vlsi.boo-all, and I think the pin list you want is baseplate/padlist.lst.

Subject: mnemo shorts test

Hi Tom,

The mnemo shorts test has died once again, but this time at a point where I can at least tell you names that are shorted. Here's the scoop:

The mnemo database is of such a size, that a single partition will not contain all the files. It died about 6 times during a single run, each time requiring certain files to be moved and linked back in. I'm going to try again, but this time using a mode of dracula which allows single files to be split across file systems. This is much slower, and the last time I tried it I believe it had bugs, but I don't remember.

There are plenty of shorts in the database in addition to floating nwnells (35 of these). There are too many geometries to even begin to generate an output file. But maybe you can find some commonality based on the node names involved in the short.

This shorts test was started over a week ago on the version at that time in /u/chip.

Here's the shorts list:

```
*/* WARNING ** TEXT : TPOUT_V          1 SHORT DISCARDED
*/* WARNING ** TEXT : SN3_ABM          1 SHORT DISCARDED

I can't discern any pattern from the list . I guess it's time for quadrant
short runs on the latest mnemo in /u/chip .

Cc: 'hestia'
Subject: Software Bringup Meeting Minutes - March 22, 1995

Software Bringup Meeting

March 22, 1995

Next Meeting: March 29 at 10:00 am.

Attendees: guarino, gmo, sandeep, jeffm, doi, gregg, lisa

New Action Items

-

None.

Review of Action Items

Item: Can a single cylinder (in an exception 'loop') lock out other cylinders?

Who: jeffm

Status: Done.

03/08 Jeff needs to talk with mws.

03/18 No progress.

03/22 Jeff is going to add a note to verify.html mentioning that we need to investigate the behaviour of a bback/exception to see if can cause other cylinders to be locked out.

Item: Terp needs to model 'guaranteed forward progress for cache miss' in the same fashion as the hardware does.

Who: lisa

Status: In progress.

03/01 Lisa has contacted mws and is implementing the same scheme used by the hardware.

03/08 Still in progress.

03/15 Progress continues.

03/22 Ditto. Jeffm mentioned that cachenastry2 doesn't work with terp.

Item: Tests need to be written to verify performance issues

Who: lisar, claseman

Status: In progress.

02/22 We need to flag performance problems as errors.

Tests could be identified (and perhaps written) to measure and verify performance of the hardware for things like cache misses, tlb initialization, exceptions, etc.

03/01 Lisar has started writing these tests.

03/08 Work continues.

03/15 Tim Claseman is assisting.

03/22 We need to generate a list of tests that we think should be written

first. Jeff suggested dcache fills, icache fills, dram and hermes accesses.

Item: Determine what additional terp features are required
(formally 'Status of Euterpe/Mnemo simulation')
Who: gmo, jeffm
Status: Pending.

02/08 Jeffm figured that in 2 - 3 weeks time there would be a need for terp/mnemo capability to support the verification effort. An issue was raised that this may not be enough time for the required additions to terp to be made.
02/15 Gmo is to create a list of requested features for terp and then he and jeffm (and others?) are to review the list and determine what will be implemented by terp.
02/22 Gmo is ready to circulate the list.
03/01 Nothing new.
03/08 Gmo has shown a group of people the list but will post it.
03/15 Still pending.
03/22 Ditto.

Suspended Items

Item: Unsnap code
Who: sandeep, guarino
Status: Suspended.

02/15 The issue of restarting the hardware from an IKOS dump was discussed and the need for an architectural snap/unsnap facility was questioned. Since the meeting it has been re-discovered (jeffm wasn't there to remind us of an earlier decision) that we are planning on loading architectural state into an IKOS simulation and not from a total IKOS logic dump. We also determined that when it came time to run some of the larger tests (real-time benchmark) we would need the capability to start an IKOS simulation from an architectural dump anyhow.
03/01 For the short term we are going to focus on a simpler approach for loading and running DVTs, the kernel, and kernel tests. This item will likely come back in April.

Item: Refine remote debugging environment
Who: sandeep
Status: Suspended

02/08 We have to decide how control (and state) is to be returned to the debug stub after a test runs.
02/15 Sandeep is not going to have time to start on this for a while.

Item: Create performance test plan
Who: jeffm, guarino
Status: [11/30] No progress as focus is on functionality.

We continue to run tests to help us compare terp vs hardware performance.
We still need to put together the actual performance tests that need to be run on the hardware.

Completed Items

Item: Build tests that access and run in a bunch of memory spaces and states.

Who: doi

Status: Done.

- 03/08 The test currently runs out of ibuffer but accesses data out of dbuf, dram, and hermes devices. The support to build the tests that specify hermes data regions in progress (mking).
- 03/18 Support for hermes (including interleave) have been added. Still working on support for execution out of different regions.

Item: Presentations on boot, gdb support, ukernel, ...

Who: sandeep

Status: Done.

- 03/22 Brief presentation on some of the more interesting chunks of code for nanoboot, boot, debugger support, ukernel entry, etc.

Item: Build microkernel tests for IKOS

Who: doi, sandeep

Status: Done.

- 02/08 Create images for boot test, snapshot images for microkernel tests.
- 02/15 doi is still working on modifying the makefiles to build the _1 and _2 versions of this. imura is creating a tool that modifies the ELF headers to have the proper real addresses (not just virtual) and gmo has modified mking to be able to understand the new headers.
- 02/22 lisar says there are still problems building this. imura is generating a code segment that will run in both rom and cerbrom that will properly initialize dram and then branch to the test (which is in dram).
- 03/01 Sandeep is going to add code to boot so it can figure out if the cerb node is zero or eight. Derek is to start building the kernel tests so they may be loaded and run on the hw simulators.
- 03/08 Ready to be built for hardware.
- 03/15 Changes were made to libc and the microkernel (end-of-test support). Sandeep has also created a dummy_boot that will allow us to preload the microkernel to speed up simulation times. These changes should be available today.
- 03/22 The null test has been built and made ready to run with the hardware simulators.

Item: Test interleaved access

Who: guarino, lisar

Status: Done.

- 02/08 Loretta started to look at this but requires terp support. Terp changes are on hold until the real-time benchmark is running again.
- 02/22 Test has been written (interleave) but has not been run on hwterp yet. Lisar is going to run this on the hardware simulator.
- 03/01 The test has been built, but not run yet. Derek is to check to be sure the hermes channels are enabled.
- 03/08 Ready to run on HW.
- 03/15 The tests generated by 'stgen' are also capable of testing interleaved accesses.
- 03/22 Loretta's test has been written (and run) and Derek's stgen also included interleaved accesses. This item is no longer being tracked.

Test Status and General Discussion

Jeff talked about current HW and test status.

Subject: Things to do list

Just a list of things to do for both Pandora-Euterpe and Hestia-Main:

*Check the electrical/gyg conversions and edits to specifications.
If we had a list of new and changed files, Howard could work on this while his database is being fixed.

*Pinout for p150_00002 is switched.

*Need Pro-E to Allegro mechanical working. License?

*Reorder the 160pin connector.

*Need global nets connected.

Anything else?
-Pattie

this while his database is being fixed.

to generate the list:
cd morpheus/gyg
cvs log BOM | more
 (note the BOM revision that is just before the date the pcb shipped.)
 (note the most recent BOM)
cvs diff -r recent_BOM_revision -r old_BOM_revision BOM >gygfiles.tobe.reviewed

the file gygfiles.tobe.reviewed contains the list of .gyg files that need to be
reviewed.

Geert,

The euterpe small lvs is running fine. There are no shorts between labeled nodes and the device counts match up fine except for 1 extra mos device in the layout. This run should be better than the last.

The compare stage is running and should be done about 10pm tonight.

Thanks,
Dave

Sounds much better. could the 1 extra device be in the corner pad test area?

Kurt Wampler writes:

Tom & I were talking about writing our own post-placement permuter which could be smart enough to permute (D,Q)/(D*,Q*) pairs, and even permute (D,D*,SEL) input groups on muxes. This would be a moderately complicated program to write, and I don't know how to quantify the benefit we would get from doing it without implementing it and testing it, but intuitively it seems like it might help.

To do this more advanced type of permutation, we would need auxiliary equivalence information in a form that can't be represented in the current ".dff" schema. This could be supplied in an adjunct file in the leafgen area. We would also need to decide what criteria were to be used for pin assignment -- netbox minimization -- route-order-dependent-gravity etc.

Even if we implemented all of this, the router would be stuck with static connectivity, since it doesn't have the ability to permute pins on the fly while it's routing.

Does an in-house GEARS-based permuter sound like it would be worth the investment of resources it would take to implement one? (Wet finger estimate: 2-4 weeks?)

Kurt-

Thanks for working on this. Let me kick it around a bit. My first reaction is that if this tool seems only applicable to Euterpe probably it is not worth the effort. On the other hand if we thought this tool would be generally useful (for example on Cronus) then it is worth proceeding. I just mentioned this to Drew and he reminded me that we will have wide (up to 17 input) fan-in dynamic AND and OR gates on Cronus. It does seem like these could profit from pin permutation. We hope to have a first route of Cronus next week, perhaps we should wait until then to see how bad or good things look and make a decision then.

auspex3:/s20	1225197	1015942	86736	92%	/N/auspex3/s20
auspex3:/s35	1847292	1587871	74692	96%	/N/auspex3/s35

auspex3:/s22	1847292	1593606	68957	96%	/N/auspex3/s22
auspex3:/s37	1847292	1688868	66060	96%	/N/auspex3/s37
auspex3:/s31	1847292	1768565	60255	97%	/N/auspex3/s31
auspex3:/s4	1240589	1063340	53191	95%	/N/auspex3/s4
auspex3:/s33	1848572	1778826	51261	97%	/N/auspex3/s33
auspex3:/s9	1240589	1066822	49709	96%	/N/auspex3/s9
auspex3:/s19	1223389	1054989	46062	96%	/N/auspex3/s19
auspex3:/s2	1240589	1074219	42312	96%	/N/auspex3/s2
auspex3:/s34	1847292	1620896	41667	97%	/N/auspex3/s34
auspex3:/s12	1223645	1064752	36529	97%	/N/auspex3/s12
auspex3:/s10	1240589	1084158	32373	97%	/N/auspex3/s10
auspex3:/s38	1847292	1737833	17095	99%	/N/auspex3/s38
auspex3:/s30	1848572	1651112	12603	99%	/N/auspex3/s30

Second, since it seems the older snapshots are not heavily accessed, we could probably free up some space by migrating them to other disks, perhaps on rama. Rama's disks now look like:

Filesystem	kbytes	used	avail	capacity	Mounted on
rama:/s9	1290069	556763	604300	48%	/N/rama/s9
rama:/s2	1077303	487301	482272	50%	/N/rama/s2
rama:/s6	1233006	895923	312423	74%	/N/rama/s6
rama:/s1	1152416	780503	256672	75%	/N/rama/s1
rama:/s3	1077303	794496	175077	82%	/N/rama/s3
rama:/s4	1233006	1076197	132149	89%	/N/rama/s4
rama:/s5	1233006	1120764	87582	93%	/N/rama/s5

The snapshots are:

Snapshot	kbytes	Mounted on
calliope-0 (w/ proteus)	113064	/N/auspex3/s28
castor (w/ proteus)	114079	/N/auspex3/s28
pollux (w/ proteus)	81891	/N/auspex3/s28
orchis (w/ proteus)	831478	/N/auspex3/s25
calliope	1617236	/N/auspex3/s30
calliope/proteus	268804	/N/auspex3/s28
euterpe	676418	/N/auspex3/s41
euterpe/proteus	997843	/N/auspex3/s23

So it looks to me as if one option to free up more auspex space would be to distribute the stuff from s28 onto rama's disks.

Anyway, I'll be around til about mid-afternoon today. Maybe we can dig up ericm or whoever, and come up with some plan. I dunno what the existing plans there may be for the auspex disks (or rama's disks, for that matter).

Subject: critical instruction sequences?

Loretta Guarino writes:

> Do either of you have any candidate instruction > sequences for performance tests?
Critical inner > loops that we should measure on the HW > simulator?
>

- 1) IDCT code (There's already a standalone test for this.)
- 2) pseudo-Huffman decode loop (stb/lib/mpeg/video/parse_mb.c:246)
(See also an earlier note I sent to Ray, reproduced below.)
- 3) Any macroblock reconstruction routines in macroblock.c
(For example, reconstruct_uni_macroblock() in
stb/lib/mpeg/video/macroblock.c:152)
- 4) The core NTSC encode loop in stb/ukernel/dev/video-out.c, lines
357 to 410.
- 5) rs_compute_syndrome() in stb/lib/fec/rs_syndrome.c

Let me know if you have any questions about this code, what context it runs in, etc.

Notes on pseudo-Huffman inner loop in parse_mb.c:

This is the heart of the DCT coefficient Huffman decoder. For worst-case input, the 12-instruction loop below should account for nearly half of the cycles spent parsing MPEG input data. (The remaining cycles are expended in a much larger body of code that compiles to several thousand instructions. Less effort has been spent on optimizing these other types of MPEG data parsing routines because they are less "dense".)

It should be pointed out that the chosen Huffman-decoding algorithm was designed with our current microarchitecture in mind. With a different set of constraints, this Huffman decoder might have been designed very differently. For example, if branch misprediction penalties and memory-op issue restrictions were less severe, it might be cheaper to compute a branch address based on the first few leading bits of the bitstream. In this case, there would be a separate code sequence for each possible combination of leading bits, allowing multiple codewords to be decoded at the same time.

The loop below performs a direct "fast" table lookup based on the leading nine bits of the variable-length code (VLC). If the VLC is short enough that these few bits completely specify the codeword, the DCT coefficients are reconstructed from data in the table entry. Otherwise, the fast decoding is aborted and control is transferred to an "exception" dispatcher that completes the decoding.

An "exception" occurs when:

- A) We've run off the end of our 8x8 matrix, which indicates the presence of illegal input data, or
- B) The VLC was not a "short" codeword. It must be one of these:
 - 1) end-of-block code
 - 2) escape-code (followed by escaped run and level data)
 - 3) "long" codeword (greater than nine bits long)

By clever encoding of the lookup table entry, we can test for all these conditions with a single branch. Each Huffman decoding table entry is a triple {LENGTH, LEVEL, RUN} indicating the length of the Huffman codeword, the value of the non-zero coefficient and the number

of preceding zero coefficients, respectively. Actually, the value (RUN + 1) is stored in the table rather than RUN, and sometimes the table contains an exception code in place of the RUN value. This is the layout of a table entry in memory:

8	16	8
Codeword Length	LEVEL	(RUN + 1) or exception code

In the loop surrounding the innermost loop (not shown), data is parsed from the input bitstream in chunks of almost 128 bits (actually 117 bits). The branch at the end of the loop detects when the single hexlet of input data is exhausted. If so, it is refilled from the memory-mapped input queue and the loop is restarted. With minimum-length coefficients, which are 3 bits long, this buffer hexlet should only need to be refilled roughly every 30 iterations of the inner loop.

The first iteration of the 12-instruction loop can be scheduled in 14 cycles. However, due to issue restrictions on store instructions, subsequent iterations must begin on a multiple of 4 cycles, so each iteration requires 16 cycles, for an IPC of 0.75. (Note: the code below is not presented the way the compiler schedules it. The instruction selection is the same, but my scheduling is somewhat better than the compiler's.)

Kurt-

Thanks for working on this. Let me kick it around a bit. My first reaction is that if this tool seems only applicable to Euterpe probably it is not worth the effort. On the other hand if we thought this tool would be generally useful (for example on Cronus) then it is worth proceeding. I just mentioned this to Drew and he reminded me that we will have wide (up to 17 input) fan-in dynamic AND and OR gates on Cronus. It does seem like these could profit from pin permutation. We hope to have a first route of Cronus next week, perhaps we should wait until then to see how bad or good things look and make a decision then.

A pin permuter would be applicable to cronus as well as euterpe. Simple permutation (as gards _could_ do) may even be more useful on cronus than on euterpe, since I think the wide fanin gates will tend to have even more densely packed targets in the atlas technology. OTOH, the fancier permutability may be of smaller benefit for cronus than for euterpe, since the class of permutations based on swapping differential signals won't exist. There should still be some usefulness, however, from being able to swap data/select pairs on muxes.

Of course, as Kurt says, it's hard to guess how much benefit this program would provide.

Subject: SDRAM location

Hi,

Because of the design requirement to duct airflow in the Pandora Euterpe module, it is optimal from a thermal standpoint to place the SDRAMs on the primary side of the pcb (the same side as Euterpe is on). This is of course different from the way it was done in Hestia, and from what has been layed out so far. It also would require a primary side smt reflow, and may have other impacts as well.

Howard, could you please take a look at the implications of having the SDRAMs on the primary side? As I am still finalizing the mechanical criteria, it would help to know how and how well this arrangement could work. Let's get together tomorrow to discuss.

Thanks,

-Tom

Subject: TSA document

Craig,

It had been my intention (and Bob has been working on this) to add to the Euterpe MicroArchitecture book all of the implementation specific details of Euterpe. For example, a complete description of the instructions supported by the Euterpe implementation in the style of the TSA.

Hence keeping a distinction between the Architecture and the MicroArchitecture documentation.

However, this has not been well received since there are contradictory implementation specific details in the TSA. In addition, it is felt that for many the depth of detail in the MicroArchitecture document is too much and they would prefer (for applications programmers) a higher level view as is provided by the TSA.

I would like to be able to address some of the inconsistencies in the TSA in the parallel with the additions to the Euterpe MicroArchitecture but as you are aware I do not have access to the source.

In addition, It may be desirable to link the overlapping documentation as a single source.

Comments? (or a pointer to the source;-)

Lisa R.

PS. Are you comfortable with the level of detail in the MicroArchitecture Books being made available along side other online documents (as is currently the case).

Subject: mnemo shorts and euterpe lvs status

euterpe lvs:

The output is basically unchanged from the last run. The number of unmatched devices is still over 4000. The iobyte and pll errors seem to have gone away, but there are now what appears to be opens in the layout.

```
NUMBER OF UN-MATCHED SCHEMATICS DEVICES = 4099
NUMBER OF UN-MATCHED LAYOUT DEVICES = 4100
NUMBER OF MATCHED SCHEMATICS DEVICES = 889160
NUMBER OF MATCHED LAYOUT DEVICES = 889160
```

The output file is:

/u/vanthof/compass/mobi/euterpe/tapeout/euterpe.compare/euterpe.lvs

Mnemo shorts:

- lower left and upper left still running.
- lower right is clean
- upper right is not. It has the following shorts:

```
VDDI
VSSI
```

There are also floating nwell regions. I'll have to try and track these down.

I have an error file for this short and it's:

/u/vanthof/compass/mobi/mnemo/mnemo_ur.err

I'll take a look at this in the morning.

Thanks,
Dave

Good question, I neglected to say that the metal ring is to my way of thinking changeable and so you one could route traces directly from the OLB pads to the SDRAM where otherwise possible. Talk to you all soon.

Subject: Euterpe lvs

Hi,

There are three types of errors in this euterpe :

1. Some inputs to the I-Cache have not been matched up and are regarded as floating (They are actually floating)
2. Two errors at inputs of TTL pads
3. There is a clock inversion, A large chunk of the clock tree is flagged and all flipflops in the register file ...

Subject: Latest top-level route

Hi,

I ran a "complete" route on the latest top-level placement (= 3 days old). This is pgroute, special nets route, linesearch and maze.

The result is about 1950 unroutes after line-search and 500 after maze.

The pgroute hurt us a bit (little M3 VREF stubs all over the place), but the special nets route should have helped.

I think it is very important to go look at the route now and understand why the wires don't route in maze. Most should be due to congestion that we are fixing but I am worried that there are a bunch that will need special attention like changing the routing order or even baseplate changes (e.g. to get to the pads). I will look at the route, Kurt, do you have some time to look at the routing results ?

As always, the stuff lives in /n/ghidra/s3/geert/euterpe/verilog/bsrc/gards2 (or it will in a short time, I will copy the files now, but it takes 10 minutes to get it all copied).

I think this one can be blamed on operator error . I failed to rebuild the clockbias cell

.

I'll start another build .

Subject: PCB Schedule

I dropped off a current schedule for PCB layout on Hestia and Pandora.

Several questions came up;

- 1) What about the Expanded Euterpe SDRAM Module?
- 2) Will we need edits to the Front panel and/or the Power Supply?

Also, Woody suggested a schematic review for the Euterpe module.

Any other questions or comments?

Subject: IMMINENT DECISION: SDRAMs on Euterpe side of PCB

We are considering placement of the various configurations of SDRAM and flash ROM on the Euterpe (primary) side of the Euterpe Module pcb in Pandora. Recall that in Hestia, these parts were on the secondary side opposite Euterpe.

This decision is being proposed because the best airflow available is on the primary side, and ducting will be simpler and less expensive. With respect to manufacturing, the micropax connector will require a SMT reflow on that side anyway, and this approach will place all the fine pitch components on the same side, which eases inspection. PCB design is assessing the routing impact, and if acceptable, we will move to DECISION, unless other issues arise.

Reviewed this extensively with Howard and the routing is simplified this way. The traces come straight out of Euterpe and to the SDRAMs.

Woody also reviewed the placement for crossovers and it won't even need to be reordered.

Howard will first start with a basic metal ring for the spacer and that will determine the placement for the RAMs. The FlashRom can also be easily moved to the top.

This is acceptable and we can move to DECISION unless there are other issues for anyone else.

Also, we will wait for the ProE to Allegro interface to determine the clamp area to place the caps. On all future boards we will place the caps, say 30-40 mils from the clamp? and on the secondary side.

Any other ideas, please let us know.

Thanks
-Pattie

Yes, follow IPC-D-275 relative to the keep-outs, treating them as if they are "protected" edges of metal and at unknown potential. I recall either .025 or .050" as the spacing for a "protected" spacing. My terminology may be off here, but see me if there is still uncertainty.

How important is it that we finish converting (most of) the acceptance tests to use tcc instead of tgcc? I got them fairly far along, but there were a few build problems that we never solved, relating to the use of the math library from onchip and dram. I'd like to know whether I should abandon the effort, or whether we should push through with getting the tests through tcc. Comments?

Loretta

I think that it is extremely important to be using tcc instead of tgcc. However, given where we are with respect to tapeout. I'd like to get the tests running as they are now and then change over to use tcc.

I can't emphasize enough how important I think that this is.

Wow, Thanks so much for the help on these items.

Had 2 more things to add to the list.

No daughter card parts showed up on the board.

The part p370_00009 The phone jack connector wasn't liked on the board because it didn't have a pin 1. I changed the part and gyg files so this should update on the board on your next package?

Thanks again

-Pattie

Subject: unpriv access to global virtual address
Cc: billz
Status: R

I'm developing x86 emulation software that in order to access memory, needs a 48-bit address space. Bit 47's special meaning confounds the problem, and my current plan is to use bits 63..48 and 31..0 for x86 segment and offset. The current cut-down LTLB only let's be use bits 63..48 when at priviledge level 2 & 3, which makes protecting other tasks from the emulation task difficult. I'd like to get the emulation task to run at priviledge level 0, native software to run at priviledge level 1, emulation system software at level 2.

This requires giving priv level 0 the ability to "bypass" the LTLB. A general capability for controlling this might involve 4 control bits (or perhaps 3, given that priv level 3 should always permit "bypass"), one for each priv level, controlling ltlb bypass for all threads (we don't need individual control per thread).

Do we have the prospect of inserting such control into the Euterpe design?

Well...the majority of nets are in common, but not all of them.

Here's
the result of an sdiff between the two lists of sorted netnames.

The results of both routes can be found in:

/n/godzilla/s2/wampler/eurip
/n/godzilla/s2/wampler/eu509

The ones in common between the two lists probably need to each be looked at to determine the cause of failure to route. One way to do this would be to make a copy of the eu509/geert_euterpe-iter.dff and call it up in REDIT for editing and try to manually route each of the disconnects.

That
usually reveals fairly quickly where the problem lies. I probably won't get to this exercise until Monday, but if someone else wants to get a head start; if some of these nets look familiar; feel free to start looking and publish the results.

- Kurt

[list deleted]

Thanks, Kurt.

This looks like good news. If we can figure out the cause for these failures then your runs suggest we may be on the home stretch- certainly as far as getting a 100% route. To meet timing we may have a little more homework.

Good work, Kurt!

To be clear, it is the TAB OLB tooling that requires that the caps be further out from the OLB pads than in the rev 2 Hestia pcb. I hope to redesign the clamp to eliminate most of the keep out that is at the four corners, where the current "x" clamp design's arms are positioned, extending out to the four mounting holes. By freeing those spaces, I hope we can pull some parts back in at the corners, but I'm afraid that the TAB tooling requirement we violated in Hestia will mitigate much benefit.

There are cost and size benefits to re-designing the clamp, however. The redesign of the clamp will not be done concurrently with the first Euterpe pcb because of the need to verify the design and the likelihood of multiple iterations. The heat sink design will also need to be modified slightly, so for the first pcbs, we need to accomodate the X clamp.

Patricia Mayer wrote (on Fri Mar 24):

I dropped off a current schedule for PCB layout on Hestia and Pandora.

Several questions came up;

1) What about the Expanded Euterpe SDRAM Module?

It's lower priority than the other boards which are essential for the base pandora system. However, if it looks like we would be stalled for any reason on any of the others we should be able to get a netlist together quickly.

2) Will we need edits to the Front panel and/or the Power Supply?

I'm not aware of anything on the front panel. I think there is a minor issue with the power module, but wayne was not planning to rev that in this turn of hestia. I'll double check that with him.

Also, Woody suggested a schematic review for the Euterpe module.

We had a preliminary one, but there were several changes. I think we should not do this until after making any edits needed to untangle the SDRAM interface in the new layout.

Any other questions or comments?

Also, we will wait for the ProE to Allegro interface to determine the clamp area to place the caps. On all future boards we will place the caps, say 30-40 mils from the clamp? and on the secondary side.

Any other ideas, please let us know.

Im concerned that tom said the distance would be greater than we had on hestia, and we should review this carefully once you have a tentative placement. I think tom is also looking at future changes in the clamping arrangement which might let us do much better on future versions.

Subject: fullchip mnemo shorts check

The fullchip mnemo shorts check finished this morning. I decided to let it run even though the short had been found to test the multi-disk option in dracula. The good news is that it worked just fine and only found a vss/vdd short. The other shorts from a previous run must have been false from the multiple times the disk filled and the jpb died.

The run time was not that much longer than a shorts check on euterpe which is also good.

Tom, page me when a new baseplate is available and I'll start up another round of checks.

Thanks,
Dave

Subject: Re: Standalone 509 route

I had a chance to examine the 146 or so persistent disconnects in the latest euterpe route. I see what's happening. Some of our non-leafmold-generated cells have targets that are clashing with the Metal2 "comb" obstructions that we activate during maze & rip-up routing to limit the amount of Metal2 used in 3-layer routing. The following cells have Metal1 targets that fall across the routing grid line at the cell edge boundary:

```
scsof1(dio_ad0ph)
xcdecsw(in_x)
xcec12cmos(cout_ab0pm)
xcmux2(d0_am)
xcmux3(q_am,d0_am)
xcnand4c(nq_am)
xcnrlatbc(q_bm)
xcvffsw(out_v)
xcvrrsw(out_v)
xvinvc(nq_am)
```

Any of these targets which fail to route during linesearch routing are prevented from routing during maze & rip-up because they're buried under the comb obstructions at the left & right cell edges.

The preferred fix would be to move these targets one track inside the cell wherever possible. I'll volunteer to make the edits, but before I make a wholesale change to all of these cells, I'll solicit comments & objections. It's not easy to disable the comb obstructions in these cells because the obstructions at present are built into the "celltype" model which is shared by all cells with the same atom footprint. It's also not desirable to eliminate the comb obstructions for these cells, because I observe many instances where long rows of these cells are placed end-to-end; this would leave large horizontal runs where lengthy M2 wires could arise.

Does anyone object to 1-track target fixes in the above cells?

- Kurt

Good sleuthing, Kurt.

>From your description of the problem, I would say the one track

>interior

move

sounds like a reasonable solution. I agree that we do not want to dispense with the m2 comb obstructions. I believe we saw a noticeable improvement in routing density and quality when we created thme. Is there a way to make a local modification of some cells and verify that a different sort of clash is not introduced?

I'd say do it if we can. Presumably, since we don't have any problems with xb cells, there must be some rule in their generation preventing targets on the edge.

It's a shame we have to make edits for the xc cells though, since they are all CMOS cell where to first order we are not concerned about performance. However, can we solve this another way? Are not the CMOS cells likely to have a footprint different from any ECL SOFA cells (because of the smaller CMOS atoms)? If so, is it possible to eliminate the combs on these footprints without affecting anything in the ECL sofa? Only the scsof1 is an ECL SOFA cell.

Once we have scsof1 fixed, it may make sense to remove some stuff from the early routing list which I think was only there to try to get some XLU stuff to route.

A process on staypuft had gone wild and had been running for a couple of days (it should have been a 15 min run of the router). I killed that process, but the .checkoutrc apparantly did not exit as a result. I then did a

chipq -k 4069

to take the whole job off the Q because it has been holding off a bunch of other stuff. However, though that entry became marked 'term', it still does not seem to have gone away, though I can't find process 3074 on staypuft.

Seq#	Target Directory	Machine(pid)	Who	Stat
1 4069	euterpe/verilog/bsrc/hc	staypuft(3074)	dickson	term
2 4075	euterpe/verilog/bsrc/cp	staypuft(15343)	geert	0:03
3 4081	euterpe/verilog/bsrc	gamorra(8306)	woody	wait
4 4092	euterpe/verilog/bsrc/nb	melpomene(2291)	billz	wait
5 4093	euterpe/verilog/bsrc	melpomene(4090)	billz	wait
6 4103	mnemo/verilog/src/dramctrl	godzilla(14304)	agc	2:19

It has however allowed the next thing in line to get started. Can you check out the Q please?

Subject: Re: Cerberus Node Number available in Exception Status Register

Date: Wed, 1 Mar 1995 15:54:40 -0800

My earlier elaboration didn't provide for desired security features of the Euterpe chip. In an earlier meeting I verbally describe a change, which may not have seen written form.

The rule should be:

if the node number is 0 or 1, boot from the flash ROM.
if the node number is 2-255, boot from Cerberus node 0.

The flash ROM needs to be accessible via Cerberus when node==0. When node==1, Euterpe should be "secure," in that the contents of the flash ROM is not accessible via the Cerberus port. For 2<=node<=255, it doesn't matter whether the flash ROM is accessible (it likely wouldn't be present anyway).

Additional security would result if other Cerberus registers are made unwritable except by Euterpe itself; this is a less direct method of potential attack, as all one can do via the Cerberus registers is set the analog levels in parts of Euterpe and Hermes to something marginal, and hope that some resulting undetected error causes a security violation. However, given the level of effort which has been used to thwart cable boxes in the past, making this impossible is probably worthwhile.

Subject: notes on TW RF MIB

This is intended as fodder for a meeting Tony proposes to hash out responses to the TW and TCI material we received last week. Since I deleted Tony's original message, I'm not sure I got all the recipients -- please forward to any I missed.

I'm writing responsory material to the TCI spec as well, but that's more complex and so isn't as far along.

- Curtis

Response to TW RF MIB: (intended as feedback we could send them.

"we're sure you've already gotten all these comments, but we just wanted to make sure...")

p 22. csmiModulationTypes. Missing codes 9 and 10 and nothing for straight QPSK. Inadvertant omission?

p 27. svcRFChannelUseIndex. Shouldn't there be an option for channels that contain both control and user information?

pp 30-38. We have a number of concerns about the components of rfChannelDescriptorEntry, detailed below:

p 32. rfChannelFEC. What is the utility of knowing whether or not a channel uses FEC? Wouldn't it be more useful to the SMA to have some estimate of the resilience of a particular channel in the face of various impairments, so that it could assign frequencies allocations of varying quality to more resilient channels? For example, the statistics table lists C/N; perhaps the channel descriptor table should list required C/N. Another potentially useful declaration, related to FEC, would be what length noise impulses can be handled error-free; still another might attempt to describe what kind of degradation is associated with a given gaussian and/or impulse noise level (relevant, e.g., to a link level error retransmit protocol).

p 33. We're not sure the modulation order and symbol rate parameters can be made to adequately describe a multi-carrier scheme like OFDM. Probably it can be made to work if you use a fixed modulation scheme about each carrier, but it seems a bit forced.

p 33. rfChannelDataRate. The description says this is the raw data rate computed from symbol rate times spectral efficiency. How about a parameter for payload rate?

p 35. rfChannelModulationOrderResolution. The meaning and examples are unclear. One normally thinks of 4QAM (sic), 16QAM, 64QAM, and 256QAM as being obtained by multiplying by 4 (i.e. by 2 in each of 2 dimensions). The example says 16 for this case. We cannot extrapolate, for example, how to describe a system that can use constellations of 32 or 128 points in addition to the above.

p 38. rfChannelPowerLevelResolution. What does "in absolute value" mean? What are the units for this number? Is there a provision for systems that set power level linearly as well as logarithmically?

p 49. In regards to the comments requesting suggestions, upstream channels would likely benefit from counters for protocol errors, collisions, other measures of contention, etc.

p 51. rfChannelCorrectedBitErrors, etc. These are specified as counters, which will wrap only occasionally. It seems that they would be more useful for network management if a couple of time resolutions were specified: bit errors in the last minute, hour, day, etc.

p 51. rfChannelSymbolErrors. There are many possible communications systems designs for

which this value cannot be reliably counted, nor is it clear to us how it adds value to the network manager.

p 52. rfChannelBlockErrors, rfChannelCarrierToNoiseRatio.
Multiple time resolutions might be a good idea for these too.

A general comment: the MIB as specified allows for certain dynamic flexibility -- mainly in going between 16QAM, 64QAM, and 256QAM. But if a channel modulator was agile between 64QAM, OFDM, and DSSS, there is no provision for describing that or dynamically changing between them. Extending the MIB to provide for this would be quite hard. The real question seems to be this: what is the advantage of having any flexibility within the "language" defined by the MIB versus using teardown and setup of channels at the channel configuration level? The latter can handle systems as flexible as you can describe, and even going between different QAM constellations will clearly require something like connection teardown and re-establishment at the receivers. To couch this comment as a suggestion: why not simplify the MIB by removing the modulation order change stuff? (The power level part is not subject to the same comment, and should stay.)

Subject: Re: notch filling in mnemo and euterpe

vant writes:

Hello,

The remaining notch drc errors in the mnemo and euterpe databases are from autogenerated tools. All custom notches have been filled. Thus I'd like to propose the following:

- add notch filling on a per chunk basis. This reduces the number of notch errors and in fact, for both mnemo and euterpe, this should eliminate all notches.

By running the notch filler on each chunk, vlsimm runs on a much

smaller dataset, and for chunks which have no violations, it runs very quick. In addition, since we know the data coming out of gards is 'on-grid', the step size for notch filling can be increased from 1 to 10 udrs, decreasing runtime by 10x.

- add notch filling before fracturing to catch any notchs created at chunk boundaries. I have not noticed any of these, so for mnemo and euterpe, I believe this will run in the time it takes to do the notch check, which is only a few hours.

We are very close to finished up both chips and if we could remove the notch false errors from the metals drc, I'd be very happy.

Good. I think this is reasonable proposal. We'll still run DRC's at the back-end (after fracture) to make sure we flag any notches that slip through.
(But what you are porposing should be the fastest way of filling notches and has the benefit that the first pass DRC will be almost, if not fully, notch-DRC clean.)

Subject: phi a/b flipped identified on Euterpe

Kurt and I had another look at the phi a/b flip this afternoon in the gtlb area. The problem turns out to be in the hookup of the gtlb to the phi a/b clock spars inside the cell crclinkt11.ly- which is only used by the gtlb.

Kurt has just completed the edits to this cell. It has been locked down and released. Tim, could you do a getbom in the Euterpe snapshot area? Then Dave can launch another LVS and, if we're lucky and we haven't introduced a metal 4 short, we'll be able to re-verify without a new Gards re-route.

If this is clean, then when Kurt's patches to the XC cells are checked in we'll soon be in good shape to run a full chip Euterpe LVS (after we get a completed route that is).

Subject: VPP power pads in euterpe

Hello,
I'm trying to generate a special layout cell for mudge which extracts out all the Metal 5 pads and node names associated with them. I'm almost done and am a bit confused about some signals from the pll section. In particular, the VPP pads. These are labeled at the top level of the pll blocks as VPP. The layout cells are 'custom_vdda_pads' and at one point they were treated special in the space transformer generation. These pads are _not_

labeled at the top level of euterpe which means that fullchip netlists don't see these as anything special. I was also under the impression that

only vdd and vss pads were allowed to be internal to the pad ring.

Are these VPP pads wired up special? and if so, how are they handled in the netlist and also how are they handled with the space transformer?

Any clarification would help tremendously as I'm also going to be running fullchip lvs on euterpe soon.

Thanks,
Dave

Subject: Re: VPP power pads in euterpe

The requirement for these pads is that they share no common current with the rest of the chip until tying into the PCB power plane. There is one pad for each of the two PLLs which are to be separately bypassed with beads/ inductor/capacitors on the board before being tied into the 3.3v power plane. Currently they are called out as 'vddep0 and vddep1' in the verilog for euterpe. They should be named in the verilog and texted in the layout with something consistent with verifying them as separate pads not connected to vdde on the chip. If the name 'vddep*' doesn't permit this due to some global combining of all signals starting with 'vdde', then this need to be changed. I believe that the analog pads on calliope were all labeled 'vpp*' at the top level.

Subject: (Fwd) (Fwd) Disk Arrays for Digital Video

I finally dug up the message that I tried to send to you before.

How are things going? I finally got my system set up, although it's not on the net yet. I went ahead and followed the flow to get a high-end Pentium system.

With Fast/Wide SCSI systems becoming more available, this might make a nice system for doing video work in the future. It's also nice to be able to run Linux on the box. It gives me the illusion have having a bit more control.

I hope this information (as out of date as it is) might be of some interest to you.

To: digvid-l@ucdavis.edu
Subject: Experiences building a Disk Array for Digital Video
Message-ID: <ab3b44d60c0210047f97@[132.197.14.175]>

I have been asked by a number of people to summarize my experiences putting together a RAID subsystem for use with digital video. This is a report on those experiences. It is longer than expected, but I have tried to write down a lot of what I have uncovered over the past six months. It also tries to explain some of the matters that must be considered when putting such a system together. For example, *why* were the sustained data rates of 3.5MB/s, 5.5MB/s and 6.5MB/s of interest to me? Read on and find out.

First, let me give some background. I do not do digital video professionally, it is purely a hobby, but I'm what you would call a "serious hobbyist". I have been doing video for a number of years, with my primary material source being underwater video (I'm a PADI & SSI instructor and teach courses in U/W video if anyone is interested!) I did my editing on a SONY EVO-9700, but there aren't any whiz-bang features in that deck, e.g. no transitions, and I prefer playing with digital over analog technology anyway.

My end-goal is full-frame, full-motion NTSC video on the order of 5-15 minutes. I'd love S-VHS/Hi8 quality, but I don't want anything less than VHS quality. Even if my final work will be output to VHS quality tape, I want to keep my edits in as high a quality as possible. In other words, I want to be able to hand a tape to someone and have them see it on a TV and not just produce little 160x120 clips for CD-ROMs.

Being a "do it yourselfer" at heart, I put together a system with a Quadra 840AV, Radius VideoVision Studio, and a RAID array. This document talks about my experiences getting that RAID array going and the ancillary things that went along with it..

Looking at the prices for pre-configured arrays, I decided to put one together myself. After all, how hard could it be? To answer that question in advance: I started this in June and I finished in January.

I started with two Micropolis 2236AVs (3GB each). These drives had reasonable capacity, reasonable speed and boasted dealing with Thermal Recalibration (TCal) well. Other than the fact that these drives a) consume a lot of power and b) run pretty hot, they are probably excellent for many applications. However, I ran into a serious problem; they don't stripe well. I put the drives on the same SCSI chain and was surprised to find that I only achieved about a 5% performance increase when striped. About 25% is more typical for RAID level 0. I eventually learned that these drives do not handle SCSI-2 disconnect/reconnect well (or maybe at all). If the drives were on separate SCSI chains, this wouldn't be a problem. Given that they were on a single chain, the ability to do disconnect/reconnect is required. OK, back to the drawing board.

While Micropolis makes a big deal of their AV drives, in reality, many new drives handle TCal fairly well. The manufacturers know that the newest large capacity and fast drives are going to be used in digital video, so they are trying to ensure their drives work well for this demanding environment. They do TCal less often and postpone TCal if a read or write operation is pending. What that means is that a new non-AV drive may do just fine for you (especially if your disk housing has good cooling). Drives from both Micropolis and Seagate are the top picks in this category. Fujitsu and Conner also have mechanisms that work well, but you need to be sure about a *particular* mechanism before you buy it. You can guarantee yourself that any old drives or new drives that aren't at the top of the curve will not handle TCal well. Based on that, I chose four Seagate Barracuda 4's as my disks. The drives are big (4GB each) and fast (7200 RPM, 8ms seek, 1MB cache) and yes, they do postpone TCal. More on the drives later.

Next: the hunt for a SCSI accelerator. There are several out on the market, but based on other people's experience in terms of both performance and reliability I narrowed down my choice to the ATTO and FWB cards. ATTO has a Silicon Express II Fast SCSI-2 card and a Silicon Express IV Fast/Wide card. Street prices are \$725 and \$990 respectively. FWB has their SCSI JackHammer card which supports Fast/Wide transfers at a street price of about \$700. Rumor had it that the ATTO card was a bit faster, so I chose the ATTO SE II (I had bought "narrow" drives). My logic was simple: with a RAID array and an accelerator, I probably would have enough performance for what I want. You'll see shortly that I was wrong.

The card arrived long before the disks, so I couldn't test things out immediately. By the time I did, the card was about 2 months old and turned out to be flaky (the system would hang when I tried to do any significant amount of I/O to drives attached to the card). I contacted ProDirect, who I purchased the card from, and their Tech support folks told me they didn't even have a system they could test it out on and, since the card was two months old, they wouldn't swap it for a new one anyway. I turned to ATTO, who preferred that I deal with ProDirect, since that is who sold it to me, but after telling them what PD said, they relented. I sent them my card and was pretty quickly told that "It worked for them" and it was returned to me. I was pissed. I tried the card in three systems (2 840s and an 800) again, with the same results. I returned the card to ATTO who still couldn't find anything wrong with it, but agreed to swap it for a new one. The new card arrived and works well (at least, it didn't crash my system).

At this point, I started running a bunch of performance tests. I have three formatting utilities: FWB HDT V1.6, Transoft's SCSI Director Pro V3.07, and CharisMac's Anubis utility V2.52s (I've recently upgraded this to version 2.53 with PowerControl (lets you control mode page settings) and RAID software, but I have not used those features yet. NOTE: I have been told that the CharisMac RAID software is *not* very good in its current release). I reformatted one drive with each of these and ran FWB's BenchTest and ATTO's performance utilities to see what I got. A short version of my results: Partition size doesn't matter (except that the FWB benchmark test thinks smaller partitions are faster), under System 7.5 cache size doesn't matter, and the FWB driver did pretty poorly.

Test configuration: Q840AV w/80MB memory; System 7.5. Partition size was 2GB. Using the internal SCSI Bus I achieved:

Driver	Sustained Read	Sustained Write
FWB	2.8MB/s	3.2MB/s
CharisMac	3.0MB/s	3.6MB/s
Transoft	3.0MB/s	3.6MB/s

As you can see, if you are using the internal SCSI bus the CharisMac and Transoft drivers were about the same with the FWB driver falling significantly behind. I don't know why; perhaps it is the driver itself, perhaps it was some mode page (the disk drive's firmware parameters) settings that the formatter set. My belief is that it is a combination of the two as an e.g. Transoft driver on an FWB formatted drive is faster than an FWB formatted drive with the FWB driver. I never looked into it enough to narrow down the cause any further. (It takes a *LONG* time to run these tests and since I didn't have to know why one was faster than another, I just cared which was faster -- there's a point where this being a hobby is an advantage!)

While these are interesting numbers (and caused me to reformat and initialize all the other drives I had access to at home and at work with the Transoft driver!), for eventual use on an accelerator card it didn't matter. When a drive attached to the ATTO card is mounted you use a driver that is in the ATTO firmware. The same is true for the FWB card and any of the current crop of SCSI accelerator cards. The performance data was obtained, and were of interest, because they provide a baseline of comparison.

I moved the drives back to the ATTO card and went to install the RAID software. I have both the ATTO ExpressStripe software and Trillium Research's Remus Limited. I started with the ATTO software (version 2.00) but the system crashed as the INIT was being loaded. ATTO gave me a free upgrade to 2.01 (tech support created an account on their system and let me dial-in via ARA to download the file, very nice of them), but that didn't work either. ATTO then gave me a Beta copy of their 3.0 software and that did work (and is much nicer to use). ATTO Tech support didn't know why 2.0X didn't work, but at that point, I didn't really care.

Reliability of the 3.00 software wasn't very good (what do you want from Beta software?!?) Occasionally, the drives would become inaccessible. While ATTO was figuring this out, I switched to the Remus software which has an even nicer interface.

Using the Remus software, I tried various configurations. I tried:

- striping across two, three and four drives

- changing the allocation unit anywhere between 16K per drive to 64K

- varied the logical file system size between 256MB and 4GB

- varied the size of the system buffer cache.

My peak performance was approximately 5.2MB/s sustained read and 4.5MB/s sustained write. This surprises me. I would have expected writes to be faster (you can do "blind writes" and return control to the application before the actual write completes). The VVS software that "find"s throughput reports about 2.8MB/s from within Premiere V4.0 using QT 2.0.

These results were achieved using a 64K chunk across either 3 or 4 drives (the numbers were close enough the difference doesn't matter), with a 1GB file system. I have heard that striping across three drives is faster than across four, but I didn't see that. Note: The FWB benchmark tests generally show smaller partitions as having better performance. The reason for this (I think) is that their random write tests have to move the disk heads less, thus reducing seek times. Sustained transfer rate, the number of interest in digital video capture, was the same regardless of partition size. I consider the effect of partition size to be an artifact of the benchmark and not a real factor in performance.

I was disappointed with the results as my "dream" was to get about 6.5MB/s through to the application. To do full-frame (640x480) full-motion (60 fields/sec) VHS quality video takes somewhere around 3MB/s if you have a reasonably clean signal. With a "great" signal, this could drop even further. Both my Sony EVO 9700 and camcorder have S-video in/out (S-video has the video signal split into two separate

signals "luminance" and "chrominance", plus separate lines for audio), so the signal is pretty good. (RGBS (Separate Red/Blue/Green/Sync) signals would be cleaner, but no consumer, and few "pro-sumer" equipment has them. RF connections (all audio and video signals combined onto one cable-typical for consumer gear) would be the worst and hence require more bandwidth for the same level of quality.

If I want S-VHS quality I'd need about 5.5MB/s. My goal of 6.5MB/s gives me a little extra so that if a random TCal hits, or the drive needs to retry an I/O, I should be able to survive it. I doubt if I will actually capture at 6.5--the difference between 5.5 and 6.5 is generally not visible, even to an experienced eye. Of course, if I'm digitizing images with a lot of detail, and hence do not compress well, that extra throughput would come in handy.

So, my 2.8MB/s was disappointing. I would have been satisfied if I had 3.5MB/s as then I could have done VHS+ quality and been happy enough, but with 2.5 that was not possible, and S-VHS quality was totally out of the question.

Now what? If you missed it, I chose the ATTO Silicon Express II card and Fast SCSI-2 drives. That was the mistake. Thinking that those drives could do 10MB/s I figured that, when striped and with an accelerator card, I wouldn't have too much problem meeting my 3.5MB/s minimums. I was wrong.

I went back to the folks I bought the drives from, Direct Connections, and they agreed to take back the drives and sell me four Fast/Wide Barracuda 4's. They gave me a 100% credit on everything I bought! It wound up costing a "few bucks" to make the switch (wide drives are more expensive), but it wasn't that bad. I had to do a little arm twisting there, but DC was *superb* when it came to handling this problem. Without any question, I can endorse people buying from them. (Tell Dave I said Hi).

Now for the accelerator card. I needed to swap the SE II for an SE IV. I went back to ProDirect, told them my sob story, etc. and they basically hung up on me. Even though they sold me a flaky card, they couldn't/wouldn't even attempt to deal with the problem, and most importantly, ATTO was willing to do just about anything to convince them they should do this (e.g. provide new packaging, certify the card was OK, etc) they wanted to have nothing to do with me. From a pure business standpoint I can't really blame them. After all, the card was five months old at this point (even though I only had a working system for about two weeks), from a customer satisfaction stand point, and from the standpoint of having nothing to lose (ATTO was willing to stand behind the "used" card), and I was going to buy the more expensive SE-IV, they didn't even want to consider it. More than the fact that they wouldn't help, it was their attitude that was bad, and for that reason, I have no intentions of going back to ProDirect again.

When Direct Connections shipped the four fast/wide Barracuda 4's, I also bought a Silicon Express IV card from them. That leaves me with a Silicon Express II to sell, so if anyone wants it, I currently have an SE-II that I'm looking to sell. A good card, just not what I needed.

Anyway, I put the system together and began running some tests. Performance was *significantly* better (I should hope so!). Using Remus Limited RAID level 0 software and FWB BenchTest to measure performance, I achieve the following:

Configuration	Sustained Read (MB/s)	Sustained Write (MB/s)
Single drive:	5.4	9.3
Two drives:	8.4	13.3
Three drives:	8.9	13.3
Four drives:	9.4	13.2
FWB (2 drives):	8.2	9.2

All tests were done on a Q840AV running System 7.5, numerous INITs (I fill the bottom of the screen on startup), and four fast/wide Barracuda 4s (ST15150W). I chose to benchmark with all INITs enabled as that would be my execution environment, rather than a minimal system (although I turn AppleTalk off, don't use a screensaver, etc). I prefer "real world" scenarios. However, I ran a subset of the benchmarks with most INITs disabled (I still needed QuickTime, VVS, Remus and the like) and found that there was no significant difference in performance results (it was slightly faster without the INITs, but not by

enough to mean anything). This surprised me, but I'm not complaining. I haven't tested the performance with and without INITs with the VVS "find" command, but I would expect that there would be a slight hit.

Except for the last test, all drives were connected to an ATTO SiliconExpress IV card with V9 PAL and Version 1.4 firmware. The partitions were all 2GB logical partition and were the first partition on the disk (additional partitions are generally slower). The final number was using an FWB SCSI JackHammer card and FWBs RAID Toolkit software. Remus is supposed to work with the FWB card, but I could not get it to do so. As the FWB card was borrowed from a friend, I did not have the time to diagnose the problem. This test was done using two drives (the most the FWB software supports). Note: One strange problem was found with the FWB card: when that card was installed, my system would not boot from my standard startup disk. Instead, it always went to a backup system folder I keep on a different drive. Once the system was up I could manually mount the other partition. Strange.

Why is read performance so much less than write? I believe the answer has to do with both the ATTO hardware and Remus software, although I haven't looked into it enough to find out. My guess is that, between the two, they are simply buffering write requests and immediately returning control to the application prior to the write taking place, never mind actually completing. The result is high (and fairly constant) write throughput).

The configuration I am using has four 4GB partitions striped across four drives. Using four drives has several advantages and disadvantages. Additional drives help read performance. As each drive has a 1MB cache, if I only access one partition at a time, I effectively quadruple my on-board disk cache. How much that is also helping read performance I cannot estimate, but the end result is the same. In addition, the large per-drive cache also helps in dealing with TCal--the drive controller can buffer data while the mechanism is unavailable during TCal. The downside is that with more drives there is a higher probability of failure. In addition, if I lose one drive I lose 16GB of data. For many, that could be enough reason to stay away from this configuration! On the other hand, for myself, I am not concerned about the loss. First, as I've said before, this is a hobby; the world will not end for me if I get set back a little. Second, I have two 8mm Exabyte tape drives on my system and do automated nightly backups with Retrospect. Even with a catastrophic failure, I won't lose much. I'm a big believer in backups!

The Radius VideoVision Studio "find" command reports about 5.8MB/s (5.9 without audio) through to Premiere. Slightly less than my optimal 6.5, but more than the 5.5 I really needed for S-VHS quality. At this point, I'm happy and am capturing and editing full-motion, full-frame video and the fish are gorgeous!

Effect of partition size: as in the past, I see a significant difference in FWB's overall index of performance based on partition size. The larger the partition, the worse the rated performance. Again, I consider this to be an artifact of the benchmark test, not a true measure. Regardless, for digital video my interest is in sustained transfer rate. Even if the performance is worse with larger partitions, my measurements show no difference in sustained transfer rate as a function of partition size.

Effect of buffer cache: I am currently using System 7.5. Apple made some significant changes to their disk buffer cache algorithms in this release. Previously, a larger buffer cache would not help performance and, especially for digital video, could hurt performance. I ran the same tests using buffer cache sizes of 32KB, 192KB, 1MB and 2MB and found no significant difference between them.

I've seen 17MB/s in ads, why aren't these numbers even close?: Several RAID vendors advertise about 17MB/s in their ads. They do so by using *two* SCSI accelerator cards. For most systems, using two SCSI channels doesn't buy you much. I've traded benchmark numbers with several people using Seagate Barracuda drives on 8100/80's (which has two SCSI busses) and their performance is about the same as mine using a single bus. However, when using an 840AV (which has a very fast NuBus), dual SCSI channels can help--in fact, if the numbers are accurate, it looks like it helps to the tune of about 30% (and about \$1,000!).

That's the good news. The bad news is that these are not real-world benchmark numbers. My bet is that the NuBus and CPU are saturated at that point and not much else is going to

go on. Given that the goal of all that throughput is to capture and play back video, when another NuBus card like the VVS is also sitting on the bus, your actual throughput may go *down*.

This is because there is too much bus contention, and limited bus performance. I recently had the opportunity to demonstrate this to an acquaintance who had such a setup--to say the least, he was surprised that his very expensive RAID array was hurting rather than helping him! He pulled the second NuBus card and we started capturing video with fewer dropped frames and more throughput. This may be counter-intuitive until you realize that you these cards are using "more than their fair share" of a very limited resource. Note that using multiple SCSI accelerators will work a lot better when we have faster busses (e.g. PCI) and faster CPUs.

Acknowledgements and comments about vendors:

ATTO: ATTO was pretty amazing. I think those guys are triple jointed because they bent over backwards for me in more ways than I could count. They were there at every step of the way, doing everything possible to both make my system work and, more importantly, their attitude was right. When my SE-IV had some funny symptoms, they volunteered to have me just ship the entire system, on their nickel, to them and they would take a look at it from there. The comment from ATTO was "you've been at this too long with too many problems, let's fix it." These guys, and in particular, Mike Woltz in tech support, are champs.

Radius: Mike Jennings of Radius's digital video team, and one of the people who has been pulling *his* hair out over at Radius to make disk arrays work well in the digital video world and I have had numerous email exchanges on this topic. While I may be the owner of a VVS, his advice and comments on my efforts have gone well beyond what one would expect from an engineer at such a company. His comments on this document (he proofread several pre-releases) have also been invaluable. Indeed, the notes on throughput requirements for various video quality and signal conditions are mostly his.

Direct Connections: As I said previously, these folks have been very cooperative and willing to help. I haven't received, and didn't]the type of technical support I received from ATTO and Radius, but they have been great to work with. If you need peripherals, I heartily recommend them.

ProDirect: A good place to avoid. I'm sure many will reply saying how they had great experiences with ProDirect--that is always true, some people have good and some have bad experiences with vendors. My experiences were uniformly bad. When ATTO tried to help, they didn't return ATTO's phone calls. It seems to me this is a place to avoid.

Final note: What is described in this document is based on my own experiences. While I have received help from many corners, I have not stated anything that I have not directly experimented with and discovered myself. The errors are therefore exclusively my own. As I have done this work on my own time, with my own (or borrowed) hardware and software, this document does not represent opinions of, and is not endorsed by, my employer. I do not guarantee that you will have the same, or even similar results.

This has been an interesting exercise. I hope to expand upon it if and when additional hardware and software become available to me. If so, I will announce the results and, eventually, make this information available electronically.

Thanks Rich,

I've have run into vddep* for lvsing the 'small' euterpe and have a
fix for that. Thanks for stopping by and helping out with the vpp pads.

The specification clearly states that the surface temperature limits of UL 1409, para 46 must be met with the "converter "on" and after temperature is stabilized". Thermal runaway, which would ensue after fan failure, is hardly a stable condition. Anyway, given the surface temperatures we measured with the fan operating, there is insufficient margin to maintain the UL limits during a fan failure prior to overtemperature shut-down.

How do you read that the stated intent of the specification is to meet UL safety limits, including the post-fan failure case, with the result of that failure being a unit shut-down?. The inference I drew from this spec is that in either normal or at worst sleep mode, the surface temperature limits must be met without a fan. We do not comply for either case with the current design, and I'd bet lots that TCI means functioning when they say "on" in this spec.

It does not address the cost of delivering and taking away the 220+ Watts.
It looks like GI's design is about 4 times lower in power, from what I hear.

If size, weight, appearance and cost had been given a lower priority over demonstration of functionality, then we might have had a Hestia that had sufficient thermal margin to deal with the ~50% unit power increase we eventually experienced, as well as easier access to debug the circuits and lower acoustic noise. What we have now, I regret to say, is really the design for Euterpe at knob setting 4, which makes no sense given the mission of the unit.

I can not imagine demo'ing the unit to customers and not getting a lot of questions about noise, reliability, and how we plan to cost-reduce. I doubt that the small size will mitigate these concerns. Pandora seems to me a better demonstrator anyway, in that it is configurable and expandable.

The current Hestia product design, when it eventually functions, will really be more of a functional appearance model, and at the projected power levels, not suitable for any deployment, even trials (I keep hearing the word trials with respect to the current design). I'm repeating myself here, but it seems to be necessary.

Subject: notch filling in mnemo and euterpe

Hello,
The remaining notch drc errors in the mnemo and euterpe databases are from autogenerated tools. All custom notches have been filled. Thus I'd like to propose the following:

- add notch filling on a per chunk basis. This reduces the number of notch errors and in fact, for both mnemo and euterpe, this should eliminate all notches.

By running the notch filler on each chunk, vlsimm runs on a much smaller dataset, and for chunks which have no violations, it runs very quick. In addition, since we know the data coming out of gards is 'on-grid', the step size for notch filling can be increased from 1 to 10 udrs, decreasing runtime by 10x.

- add notch filling before fracturing to catch any notchs created at chunk boundaries. I have not noticed any of these, so for mnemo and euterpe, I believe this will run in the time it takes to do the notch check, which is only a few hours.

We are very close to finished up both chips and if we could remove the notch false errors from the metals drc, I'd be very happy.

Thanks,
Dave

Subject: Target edits

Hi,

I've edited the following 16 hand-generated leaf cells to move M1 targets which were falling under our M2 "comb" obstructions used to limit M2 length generated by the maze & rip-up routers during final routing. All 16 cells passed LVS after the changes were made.

ealnf36s9x4a.ly
scsofi.ly
serbiflop.ly
xcdecsw.ly
xcecl2cmos.ly
xcinvc.ly
xclatbc.ly
xcmux2.ly
xcmux3.ly
xcnand2c.ly
xcnand3c.ly
xcnand4c.ly
xcnrlatbc.ly
xcvffsw.ly
xcvrrsw.ly
xcweakc.ly

The cells have been checked in, locked down, and releasebom'ed. I will submit an update-chip to re-make /u/chip's version of the GARDS FDL files for these cells.

For the snapshot version, we'll need a getbom in proteus/compass/layouts, and a make in proteus/gards. I'll assume tbr will take care of the snapshot updates. (Tim, you might want to check with Dave to make sure that picking up these changes doesn't invalidate currently-running LVS jobs -- if any of these cells are used in the "small" euterpe design currently undergoing LVS, the new layouts might cause shorts or opens with the original GARDS routing.)

If I've broken anything, please page me and I'll try to put things aright.

- Kurt

I can not imagine demo'ing the unit to customers and not getting a lot of questions about noise, reliability, and how we plan to cost-reduce. I doubt that the small size will mitigate these concerns. Pandora seems to me a better demonstrator anyway, in that it is configurable and expandable. The current Hestia product design, when it eventually functions, will really be more of a functional appearance model, and at the projected power levels, not suitable for any deployment, even trials (I keep hearing the word trials with respect to the current design). I'm repeating myself here, but it seems to be necessary.

I think we have to consider the current point of comparison, at least in the minds of some of the people who have seen Hestia at board meetings, is the current Orlando trial, where I gather it was even necessary to design and deploy special furniture to accomodate the many components necessary to get demo functionality. Bear in mind among this was an SGI workstation, certainly something containing a fan. If we feel in bad shape with the degree of work we will need to do to get to a low cost fanless design, we're a lot further along than that system.

I think the reality is that real deployment of this kind of technology (from anyone) is a lot further out than the optimistic predictions of a year ago suggested. Mouss has made it clear that in the short term he's looking for opportunities which can make use of our existing chipset, either at the nominal power levels for products where fan cooling is acceptable, or at lower power levels where reduced performance is acceptable. Accordingly we have had most of our effort focussed on the final stages of completing these implementations. I for one feel it's vitally important we finish what we have and get real hardware into the hands of our applications developers as soon as possible. A serious power reduction redesign will be a major undertaking and while we have done enough to believe there is scope to find order a factor of 2 (and I realize this may not be enough), it would have been a mistake to have taken a reset and increased risk to attempt this before we have got out of the starting block.

To get more than the factor of 2, will I think involve rethinking the whole system not just employing circuit tricks. Curtis has already alluded to the possibility of employing more dedicated hardware (but which would still be integrated) to reduce the processing burden in Euterpe. This possibility should be on the table, as should a possible repartitioning of the analog and digital functions in Calliope once we have hard data on the performance of the analog and RF functions in our process. We should combine this analysis with a serious analysis of cost reduction options, since clearly the two are very closely intertwined.

Subject: phi a/b flipped identified on Euterpe

Mark Hofmann wrote (on Mon Mar 27):

Kurt and I had another look at the phi a/b flip this afternoon in the gtlb area. The problem turns out to be in the hookup of the gtlb to the phi a/b clock spars inside the cell crclkintl1.ly- which is only used by the gtlb.

Kurt has just completed the edits to this cell. It has been locked down and released. Tim, could you do a getbom in the Euterpe snapshot area? Then Dave can launch another LVS and, if we're lucky and we haven't introduced a metal 4 short, we'll be able to re-verify without a new Gards re-route.

I assume what we need here is an update to the euterpe/proteus snapshot to get this layout, rather than the euterpe area itself.
I'll fire it up now.

If this is clean, then when Kurt's patches to the XC cells are checked in we'll soon be in good shape to run a full chip Euterpe LVS (after we get a completed route that is).

What's the eta on release of these edits? It may be expedient to pick these up in the same build.

That may not be the case for the product design. From my perspective, the issue boils down to dealing with a concentrated heat load vs. a distributed and lower heat load. Even the Indys that are the basis for the Orlando trial unit are ~100W, with the MIPS processor an order of magnitude lower than our current power dissipation. Assuming that the competitors keep using low power&density twisty little processors, they have a mechanical product design and probably a total cost advantage. Not to deny that we may have other unique advantages, but we must be clear on this disadvantage and its cost.

Agreed, but don't we need to have a better defined plan for getting to the high volume solution that these applications would run on? Also, I still have doubts about whether we shouldn't have taken a reset on the thermal design, given where we are today. We could still reset, but only if the return is there to justify it. That is one issue we need to resolve when we consider producing any more Hestias beyond what we've purchased parts for at this time. Another is how much effort to put into stretching the RO's specs to meet the increased requirements.

Typically, along as some flexibility is maintained, the earlier these analyses and trade-offs are made, the lower the cost of development and the shorter the time to market. Do you think that with Euterpe design almost completed we are close to the right time to begin work on this, or must we wait until Calliope and/or Euterpe are brought up to begin

such tasks?

One

example of an issue that hinges on the answer to this question is whether simply using lab supplies with Hestia may save some misplaced effort, if the final product uses a synchronous rectifier instead of a switcher.

xcecl2cmos.ly
xcinvc.ly
xclatbc.ly
xcmux2.ly
xcmux3.ly
xcnand2c.ly
xcnand3c.ly
xcnand4c.ly
xcnrlatbc.ly
xcvffsw.ly
xcvrrsw.ly
xcweakc.ly

The cells have been checked in, locked down, and releasebom'ed. I will submit an update-chip to re-make /u/chip's version of the GARDS PDL files for these cells.

For the snapshot version, we'll need a getbom in proteus/compass/layouts, and a make in proteus/gards. I'll assume tbr will take care of the snapshot updates. (Tim, you might want to check with Dave to make sure that picking up these changes doesn't invalidate currently-running LVS jobs -- if any of these cells are used in the "small" euterpe design currently undergoing LVS, the new layouts might cause shorts or opens with the original GARDS routing.)

Good point, but too late! The getbom has been running for some time now and has picked up these layouts. I was under the impression that we needed the update asap to correct another layout edit to correct the massive clock hook up mismatch.

If I've broken anything, please page me and I'll try to put things aright.

Will do!

OK. I'll start the make as soon as the getbom completes. Hopefully it will be fast running. I'm not sure what needs to be remade in the euterpe area after the proteus update is done to pick up the clock fix. I think Tom will need to handle that.

Agreed, but my reading of the current situation is that from Mouss's perspective, it's much more important we find a second channel for our technology (at current performance/power) than getting further into a single customer situation which is itself clouded with regulatory imponderables at this time. I think it's partly for this reason that mouss has backed off the urgency of the major redesign we clearly need.

As regards the RO, I was under the impression from noel, that we have mainly been investing time, not cash \$ in the RO improvements, since the arrangement with RO allows them to sell the module as a generic design to anyone, not just MU. This could be wrong information. If so, we should certainly be reconsidering if we should spend any more there.

We are close, and in fact I owe curtis some discussions on exactly this wrt Euterpe. However, I think for Calliope we have to have some real characterisation data on the process before we can determine if other analog/digital partitioning might make sense.

As far as synchronous rectification goes, would we expect this to materially affect the switching noise? As I understand it, this technique is really just a way of simulating rectifier diodes with essentially zero forward bias voltage. Doesn't the same basic switching still take place?

Tom Eich wrote (on Mon Mar 27):

Tim, one thing I wanted to mention that I've not discussed with you is that the lack of planning and product management wrt Hestia and its implications for ultimate success are not lost on the product-oriented engineers (hw or sw). To paraphrase an engineer (since departed) who has been exposed to the quite large and now solo SGI set-top effort, "they have better odds of having deployable hardware in 1 1/2 years than microunity, based on technical risk and total product design capability". This problem cannot be blamed on poor internal communications at MicroUnity, as some would have it.

I have to admit that I am probably as guilty as mouss in not taking into consideration the true scale of the work involved in getting something such as Hestia to real high volume. Mouss tends to oversimplify and consider the box as "just a package", which certainly does not do justice to the quality of the work you have done. My system level experience has all been with relatively modest volumes where it has been possible to wing it all too often.

One of the reasons I'm pushing (and I don't mean to push you, as you're understandably too busy and it's not your responsibility anyway -- Jack and ultimately Mouss is my target here) for a more fully realized plan of attack is for the sake of the product oriented engineers like you and me.

I feel I have not done as much as I should have, but I'm much happier dealing with the technical issues, and not good at the kind of wheeling and dealing that seems to be an essential part of getting a revolutionary product like this into a brand new market. As a result I have had almost no involvement in such discussions as there have been with the potential customers.

Until that goal is realized, I personally can't muster the motivation to spend the excessive effort that I did during the last 6 months of '94 on Hestia. Also, I know my limitations, being an ME, and can't honestly assume responsibility for this management requirement. So I guess there is a selfish motive at work here also, but I believe it coincides with several practical reasons for better planning and product management.

I understand.

Btw, any word on the Steve Manser offer status?

As far as I know an offer has been extended. I have no idea about how it was received.

ps: Craig really dismayed me with his lawyerly but illogical response on

the TCI fan ban issue. I thought he was historically unenthusiastic about the set-top box as an application for our technology(?) I suspect he's upset with me, as he brushed past me in the hall this afternoon, but I can't abide such nonsense.

Craig has always I think wanted to build mainstream "computer" type systems. I know he was one of the main opponents to cutting the FP functionality which was so necessary in my mind to have any shot at the set top application with Euterpe. However, that said, in some presentations I've participated in he has done a good job of rationalizing most of the decisions we did take. He has never been a believer in the ECL circuit technology we have been using.

I think in all this we should not lose sight of the fact that even if we had the perfect product (per the TCI spec), it's far from clear if there is a real prospect of them being bought in volume in the near future. As I understand it, the big interest in the cable modem and the InterNet access services is happening for two reasons. First it's just not clear if the FCC will allow enough freedom for the cable companies to be able to raise the capital needed to deploy the technology. Second, it's not clear that the kinds of services previously envisioned (eg near video on demand) will ever result in enough revenue to justify the enormous investment. In contrast at present the InterNet is completely unregulated, and growing at a CAGR that no-one can ignore (eg WWW activity increasing at > 25%/month (yes, per month!)).

Tom Eich wrote (on Tue Mar 28):

Thanks for your reply. I hope Jack can wade through this thread and still be willing to pick up the product definition mantle.

Thing about cable modems that worries me is that historically modems have always quickly become commodities with each successive technology step (V34 is now <\$80!). The market seems like it would be even less tolerant of the competitive disadvantage of our approach than the set-top, but as you point out, it is growing like a weed, and 64QAM is a more rarified level than what's come before. If it does become commoditized, we won't likely find much profit there.

I absolutely share these concerns, and I think I am actually in mouss's bad books right now for vociferously stating that position at a recent meeting!

The other complaint I've heard from mainly sw types is with respect to adopting our current architecture to cable modems by spreading the QAM sw over the 5 threads, with each thread perhaps at 40-some MHz. Probably do-able (per Larry Yamano), but extremely suboptimal. If this product really gathers steam, can the architecture be modified to tailor it to the specific requirements?

I think we'd have to and I think the action is with us hardware folks and tony right now to figure out what the right combination of microarchitecture and technology is for various possible product points. Ther is a lot of flexibility at the micro-architecture level with very little impact at the architectural level. For exmple, I know tony thinks there would be real potential in a single threaded 100MHz design for embedded applications. We need to get the current Euterpe off our backs so we can put serious thought into this!

I know of no clock fix in the euterpe area . The VDD/VSS short
found several days ago by the mnemo SHORT test was due to
operator's error -- the build was not done in the correct sequence .

Subject: Pin permutation of XBOR & XCNAND D-inputs

Hi,

Under the category "pulling out all the stops" we would like to incorporate the following extras into the general place/route strategy:

- 1) Add permutability properties to the D-inputs of all XBOR and XCNAND family gates. This can be done in topt or emerge by inserting the following code into the "emerge.tab" or "power.tab" files.

```
# Add permutability attributes to XBOR... and XCNAND... D-input pins
addportproperty xbor.* d.* EQ_CLASS PERMUTE
addportproperty xcnand.* d.* EQ_CLASS PERMUTE
```

Is /u/chip/proteus/misc/emerge.tab the right place to insert this code?

- 2) Ask GPLACE to try harder with its component flipping optimization, and ask it to perform pin permutation at exit time. This would change our standard gplace.nic incantation to: ("|" indicates changed lines)

```
readpif {design}.pif; ok
makeauto use; ok
iparam sweeps 0;
| iparam iterations 5;
iparam algorithm hper_netlength;
improve use; ok

I know of no clock fix in the euterpe area . The VDD/VSS short
found several days ago by the mnemo SHORT test was due to
operator's error -- the build was not done in the correct sequence .

I think that was fully understood. Some cell inthe gtlb was getting hooked to the SOFA
clock backwards.

Tim

Hi Tom,

Oops. Sorry I left you off the mail on this one. Here's what we found:

>From hopper Mon Mar 27 15:24:39 1995
Subject: phi a/b flipped identified on Euterpe
To: geert (Geert Rosseel)
Date: Mon, 27 Mar 95 15:24:39 GMT
Cc: bpw (B. P. Wong), wampler (Kurt Wampler), tbr (Tim B. Robinson), vant
X-Mailer: ELM [version 2.3 PL11]

Kurt and I had another look at the phi a/b flip this afternoon in the gtlb area. The problem turns out to be in the hookup of the gtlb to the phi a/b clock spars inside the cell cclkint1.ly- which is only used by the gtlb.

Kurt has just completed the edits to this cell. It has been locked down and released. Tim, could you do a getbom in the Euterpe snapshot area? Then Dave can launch another LVS and, if we're lucky and we haven't introduced a metal 4 short, we'll be able to re-verify without a new Gards re-route.

If this is clean, then when Kurt's patches to the XC cells are checked in we'll soon be in good shape to run a full chip Euterpe LVS (after we get a completed route that is).

-thanks,
hopper

Subject: Pin permutation of XBOR & XC NAND D-inputs
Follow Up Flag: Follow up
Flag Status: Completed

Kurt Wampler wrote (on Tue Mar 28):

Hi,

Under the category "pulling out all the stops" we would like to incorporate the following extras into the general place/route strategy:

- 1) Add permutability properties to the D-inputs of all XBOR and XC NAND family gates. This can be done in topt or emerge by inserting the following code into the "emerge.tab" or "power.tab" files.

```
# Add permutability attributes to XBOR... and XC NAND... D-input pins
addportproperty xbor.* d.* EQ_CLASS PERMUTE
addportproperty xcand.* d.* EQ_CLASS PERMUTE
```

Is /u/chip/proteus/misc/emerge.tab the right place to insert this code?

As far as I am aware all the relevant rules in the standard flow ultimately derive their emerge.tab files from this one. So, I'd say yes this is the right place.

- 2) Ask GPLACE to try harder with its component flipping optimization, and ask it to perform pin permutation at exit time. This would change our standard gplace.nic incantation to: ("|" indicates changed lines)

```
readpif {design}.pif; ok
makeauto use; ok
iparam sweeps 0;
| iparam iterations 5;
iparam algorithm hper_netlength;
improve use; ok
writenof {design}.nof; use; ok
| exitswapsave
exitnosave
```

Is it appropriate to make this change in both of these places?

```
/u/chip/proteus/Makefile.rules
/u/chip/euterpe/verilog/bsrc/Makefile.vo
```

If we are going to make these changes as standard in proteus (and we probably should), then you should also check the mnemo Makefiles for additional places.

Subject: Pin permutation of XBOR & XCNAND D-inputs

Hi,
This was forwarded on to me and I hope I understand what is going to be tried, and if I don't then, please ignore me. There is a nasty problem which will occur if permutability is implemented:

LVS won't work.

The first thing dracula does is flatten the netlist into discrete transistors and then use that to verify against the layout. If pins are permuted, the netlist no longer matches the layout.

ISS does handle permutability, but ISS does not like the baseplate methodology and we have not built up the necessary hierarchy information for ISS on any of the chips. To use ISS requires changes to the existing hierarchy.

We could 'in theory' extract what has been permuted and feed that back into the netlist, however, we are now changing the original input netlist to match the layout and that could hide potential problems. The VII/VRR lines are currently done in this fashion, but those connection changes don't directly impact logical connectivity.

We must really really really want to do this, and if we do, we must have an workable solution to the netlist munging.

Thanks,
Dave

For the 5PM disturbance, I've releasedbom'ed the following files to implement pin permutation on xbor & xc nand gates, and to increase the iteration count for component flip optimization to a maximum of 5 passes:

```
proteus/misc/emerge.tab
proteus/Makefile.rules
euterpe/verilog/bsrc/Makefile.vo
mnemo/verilog/src/Makefile.vo
```

If I made any fatal typo's or otherwise broke things please let me know & I'll attempt to correct.

Sorry, I was at a restaurant. I'm now moving /u/chip/hephaestus and /u/chip/orchis to /n/rama/s10 to clear some space for the immediate term.

Do you know what was building when the disk filled? I've been watching the free space on that disk for a while, and although it was low, there had been a pretty steady 35Meg free... obviously not a big enough margin.

No. I have stuff running in the euterpe snapshot, but that should not be putting anything /u/chip. I discovered it really 100% full when I could not write out the .cshrc.interactive from the editor! I found an 8MB core file to remove, which let me write it out, but it filled up again pretty quickly.

Looks like it got past gplace this time. Very strange. Surveying the gplace binary, I find dozens of "Ran out of memory" strings in it; apparently there are many ways it can run out of memory(!) Was the failure earlier today also on nosferatu? I suppose there could have been a transient process (or some big job that was just finishing up) that had most of memory & swap space tied up, and then relinquished it just after gplace crashed.

Anyway, I don't see any other obvious clues upon first examination. Perhaps rebooting nosferatu would be worth a try.

Interesting, because overnight I have built nb in the snapshot area from this same BOM with no problem.

BTW, there is something about the mail header (I think the doubly nested parens) which means that when I try to reply wit 'F' in VM, the cc list gets dropped. I only ever seem to have this problem with mail from you, and then only sometimes!

Well, I tried to gdb the core file with the topt binary and it apparently died when trying to flatten the netlist. I've gotten enough information to run some tests and sure enough, it is getting a segv in the flatten routine of nb.edif. Something has changed somewhere in the edif netlist format and topt doesn't like it.

So, sure go ahead and blow it away.

Thanks,
Dave

Sheesh, This day is starting out crazy for me already... The gdb died alright,
but because of a silly mistake on my part. The flattening works, so I'm
confused about this one... rerunning the job with enough space might fix it?

Thanks
Dave

I have BOM 67.0 (from top level 266.0), and it ran for 10 iterations without converging, and then gave up. Are you expecting it to converge?

Well, let's see. *My* dr gards run converged in 7 iterations. However, I don't believe I've gotten it to converge in /u/chip using the .checkoutrc script recently. Metal 3 routing is very tight, and I've noticed great variations in the number of iterations to converge and the number of unrouted nets due to perhaps small cell changes (I alternately point my euterpe/proteus at /u/chip/proteus or the snapshot, at the moment /u/chip/proteus) or routing order of the nets.

So, yes I expect it to converge; but, no, I'm not surprised it doesn't. Let me know how I can be of assistance.

Please look at the -iter results in the s41 snapshot area and see how it looks, and how many paths have failed to make it. As it was iterating I noticed is started out very ragged at the top and there has obviously been a lot of pippacking going on which I would expect to slow down the convergence.

This core file can be deleted.

I'm very confused. We had several jobs die last night from 'bus errors'
in topt. The binary hasn't changed, and when I run them this morning,
I'm not seeing the errors.

This will take some more debugging work...

Thanks,
Dave

Yesterday , that disk got full a couple of times . I think whoever
did it cleared enough to free 194MB . Usually there isn't much
space available . I must have gotten 100+ messages from ericm asking
me to clean up even though I use only 80MB of space .

According to agc , who kept his sources on the auspex , and
GARDS results on the scratch disk , 400MB is about the minimum
he can tolerate for the 3 designs that he checked
out (mnemo, calliope, mnemosyne) .

If I extrapolate to the 4 designs I have (mnemo,calliope,euterpe,cronus)
I would say at 600M is about the minimum for me . I don't keep as many
verilog dump files around but I do have all the baseplate/layout stuffs

Subject: Re: dr doesn't converge

Tim,
Re: dr doesn't converge

I can't account for the differences in my run versus the run in .../s41/euterpe-snapshot/... but for that run, there are several nets in the lowest quadrant which don't route because all of the vertical routing resources have been used up. A way to fix this might be to introduce a column of spacer cells which keep the real cells further apart and create more, local vertical routing resources. Do you suggest I try this?

Subject: rich_euterpe

geert,

i was just looking at my toplevel route and still see a couple of problems. i moved the sumation logic to the lower side of es whwere there was some extra space. it caused a couple of unroutes in that area.
does my makefile target wire the longest nets first as in your jobs ???

also i noticed mc data path is not pitched matched exactly.
for a while we were pifpacking this one alot and gates have wandered out of the bit pitch.

Subject: Re: verilog?- last chance...

Tim B. Robinson writes:

Sorry, mark, kept meaning to respond on this one. We are going through a peak right now, which I think will drop off shortly once Euterpe is finally behind us. Is there a logfile anywhere that shows the usage? I know lisar has failed to get a license a few times, but usage is peaky. If we are near the limit much of the time during the day, we should do it, if we typically have a couple of spares and only hit the limit occasionally I'd hold off. \$35K is a lot, and the downside is really only the delta discount.

Okay.

Here's what I come up with from the log file:

>>>>CURTIS

I understand you are developing an OS and a compiler for your media processor (MP). What is your OS like? You also said that you have developed a microkernel OS to run UNIX on your MP. You also mentioned that Windows NT is being ported on to MP. In these cases, what kind of performance do you expect to get out of your MP running UNIX or NT?

We are currently working on 2 separate OS's for our mediaprocessor: a real-time microkernel intended to support certain kinds of small-memory applications, and an OSF port intended to support applications with larger memory, less cost sensitivity, and more reliance on traditional and/or pre-existing software. In understanding these, it is important to know that our mediaprocessor implementation is a 5-way multiprocessor sharing a memory system -- a single datapath in which 5 instruction streams execute in round robin, each with separate registers, and communicating through the memory system and with the support of multiprocessor synchronization instructions.

The OSF port will be most appropriate for products containing Mmemosyne DRAM and PCI controllers. We plan to modify the existing multiprocessor support in OSF to work with the shared memory model of our chip implementation.

The microkernel is best suited to running a single application at a time, though it is capable of running more than one. It is designed to provide i/o support through device drivers, support for organizing computation through software threads of control, and support for minimally trusted applications through its use of the TLB and protected gateway features of the architecture. (Note that trust in this sense applies to potential maliciousness but perhaps even more importantly to poorly debugged code. The ability to develop code in a controlled, protected environment is a time-to-market enhancer that has been little appreciated in embedded systems, or even PC/Mac software.)

Generally speaking, the microkernel is designed to provide the kinds of support enumerated above but to stay out of the way as much as possible while doing so. For example, memory protection is arranged so that page mappings need never be changed (for to do so would decrease predictability and make real-time programming harder). Also, the user-level interface to device drivers is through shared buffers; Unix-style i/o requires either an extra memory-to-memory copy or else page mapping.

As to Windows NT, no port is currently underway, though negotiations are in progress.

Performance under Unix or NT will be a fairly sensitive function of the kind of applications run under them and their disposition in the physical memory space. One interesting scenario would be to run Unix or NT applications in a single one of the multiprocessors and to run specialized, real-time media code in the others. The Euterpe design allows this to be done for many applications without memory system interference.

I assume MPEG1 and MPEG2 decoding can be done realtime on your MP.
Thus,
this MP can be used for the ATV (U.S. all digital version of HDTV) set?
Can MPEG1 and MPEG2 encoding also be done realtime?

We have focused intensely on MPEG2 MPML decoding. MPEG1 CIF decoding is a subset, which we can do easily. HDTV decoding is probably within our grasp, but we need to investigate memory bandwidths, worst-case use of B frames by the encoder, etc. We have not actually reduced MPEG encoding to practice. We have developed and evaluated a surprisingly fast

motion estimation algorithm, equivalent to exhaustive search. This makes us think broadcast quality MPEG2 encoding is an objective worth trying for.

...
Is your MP also suited for 3D CG rendering, etc? Can it be used as a virtual reality engine?

The microkernel incorporates a 2D 24-bit color graphics package with anti-aliased text and various other features. We have not seriously investigated 3D algorithms yet. Based on preliminary studies, the instruction set appears very suitable for rendering algorithms. Given that there is no floating point, it is somewhat less suitable for the geometry calculations that preface the rendering operations, but these are usually fewer in number anyway.

Software Bringup Meeting

March 29, 1995

Next Meeting: April 5 at 10:00 am.

Attendees: guarino, gmo, jeffm, doi, gregg

New Action Items

-

Item: Is smux aliased to smas?

Who: jeffm

Status: New

Item: Modify tests in diag tree to use tcc instead of tgcc

Who: guarino, jeffm, doi

Status: New

03/29 Loretta has changed the diag tests to use tcc instead of tgcc but has not checked in the changes.
Lisar wants these changes to be made after we are able to run the tests successfully using tgcc.

Review of Action Items

Item: Can a single cylinder (in an exception 'loop') lock out other cylinders?

Who: jeffm

Status: Done.

03/08 Jeff needs to talk with mws.

03/18 No progress.

03/22 Jeff is going to add a note to verify.html mentioning that we need to investigate the behaviour of a bback/exception to see if can cause other cylinders to be locked out.

03/29 No progress.

Item: Tests need to be written to verify performance issues

Who: lisar, claseman

Status: In progress.

02/22 We need to flag performance problems as errors.

Tests could be identified (and perhaps written) to measure and verify performance of the hardware for things like cache misses, tlb initialization, exceptions, etc.

03/01 Lisar has started writing these tests.

03/08 Work continues.

03/15 Tim Claseman is assisting.

03/22 We need to generate a list of tests that we think should be written

first. Jeff suggested dcache fills, icache fills, dram and hermes

accesses.

03/29 Tim has come a long way up the learning curve and is now focused on producing the first 4 tests that were requested.

Item: Terp Feature Status

Who: gmo

Status: New

03/29 Gmo reviewed the updated list. Here it is.

Simulator to-do List 3-29-95

- o Holes in address spaces => machine checks
 - mostly done.
- o Address interleave
 - mostly done.
- o Reflect "forward progress" change in the hardware
 - complete and being tested.
- o Ifetch protection granularity
 - performance vrs accuracy tradeoff
- o Fetch instructions as octlets
- o Simulate Ifetch queue
- o Accuray wrt HW simulator(s?)
- o Better latency model for Calliope accesses
- o Implement hardware configuration through Cerberus regs (SDRAM parameters?)
- o Checkpoints/Snapshots
- o Model PCI
- o hermes and cerberus timeout machine checks
 - question of whether they are supported
- o ability for terp to load hermes sections
 - not needed yet by verification group

Suspended Items

Item: Unsnap code

Who: sandeep, guarino

Status: Suspended.

02/15 The issue of restarting the hardware from an IKOS dump was discussed and the need for an architectural snap/unsnap facility was questioned. Since the meeting it has been re-discovered (jeffm wasn't there to remind us of an earlier decision) that we are planning on loading architectural state into an IKOS simulation and not from a total IKOS logic dump. We also determined that when it came time to run some of the larger tests (real-time benchmark) we would need the capability to start an IKOS simulation from an architectural dump anyhow.

03/01 For the short term we are going to focus on a simpler approach for loading and running DVTs, the kernel, and kernel tests. This item will likely come back in April.

Item: Refine remote debugging environment

Who: sandeep

Status: Suspended

02/08 We have to decide how control (and state) is to be returned to the debug stub after a test runs.

02/15 Sandeep is not going to have time to start on this for a while.

Item: Create performance test plan
Who: jeffm, guarino
Status: [11/30] No progress as focus is on functionality.

We continue to run tests to help us compare terp vs hardware performance.
We still need to put together the actual performance tests that need to be run on the hardware.

Completed Items

Item: Terp needs to model 'guaranteed forward progress for cache miss' in the same fashion as the hardware does.

Who: lisa
Status: Done.

03/01 Lisa has contacted mws and is implementing the same scheme used by the hardware.
03/08 Still in progress.
03/15 Progress continues.
03/22 Ditto. Jeffm mentioned that cachenas2 doesn't work with terp.
03/29 Lisa has implemented fixes but is unable to get cachenas2 to fail with the old simulator. Jeff and I were unable to reproduce the failure either. Lisa is going to check in the fixes and we are going to call this one done.

Item: Determine what additional terp features are required (formally 'Status of Euterpe/Mnemo simulation')

Who: gmo, jeffm
Status: Replaced with new item (Terp Features Status).

02/08 Jeffm figured that in 2 - 3 weeks time there would be a need for terp/mnemo capability to support the verification effort. An issue was raised that this may not be enough time for the required additions to terp to be made.
02/15 Gmo is to create a list of requested features for terp and then he and jeffm (and others?) are to review the list and determine what will be implemented by terp.
02/22 Gmo is ready to circulate the list.
03/01 Nothing new.
03/08 Gmo has shown a group of people the list but will post it.
03/15 Still pending.
03/22 Ditto.
03/29 Replaced with item 'Terp Features Status'

Item: Is unix test modified to work around the ltlb/gtlb enable stuff?

Who: iimura, doi
Status: New/Done

03/29 doi talked to iimura before the minutes were complete. This modification has been made (and will be removed when the hardware fix is implemented).

Test Status and General Discussion

More of the acceptance tests ran successfully on the latest BOM.

From: Loretta Guarino [guarino@microunity.com]

Subject: March 27 Benchmark Meeting

We considered hardware configurations that we might have to work with in the coming months:

Cronus only (August or September)
Euterpe only (September?)
Euterpe + Mnemo(??)
Euterpe + Calliope(September?)

It seems likely that our initial system will be either a Cronus or Euterpe. The major differences between these two systems would be speed. Most likely Euterpe won't be air-bridged, so it won't run at 1GHz. Bill H. says at current power a non-air-bridged Euterpe should run at 400MHz.

Rev 0 Calliope will be processed before either Euterpe or Mnemo, so based on current progress it looks like a non-air-bridged Calliope with some functionality might be available as soon as Euterpe.

For a Cronus or Euterpe system, we'll develop versions of the Digital TV and maybe the Analog TV applications that don't use calliope. They would load initial data into DRAM and write a few frames worth of output into DRAM. This will let us test Euterpe first, before we take on the added complexity of Calliope.

For a Euterpe+Mnemo system, we'll modify this basic Digital TV application to write video output to a VGA buffer; this would require adding support for the PCI graphics card to the Microkernel.

For a Euterpe+Calliope system, we would focus on testing Calliope. In addition to the existing calliope diagnostics and Microkernel tests, we'll write simple tests to drive audio-out and video-out and expand the IR tests. We can also look into bypassing part of Calliope and receiving baseband QAM, so we can start testing our QAM code even if the RF portion of Calliope isn't working. We should be able to run the UI benchmark on this system, and the RF QAM receiver. For bring-up, we are assuming the availability of accurate clock sources.

We need to look at all our tests with an eye on how to make them work on a system with a much slower clock than we have been planning for. As much as possible, we'd like to avoid having to completely restructure code just for testing in this environment.

The non-calliope tests can probably just run more slowly. It may be possible to develop tests that use a slower Euterpe+Calliope to demod a lower baud-rate signal. Curtis has talked with Graham who is investigating the technical issues. Curtis will organize a separate meeting to investigate QAM.

Some general decisions:

1) We'll remove DLWS from the Digital and Analog TV benchmarks for now; we aren't using much of its functionality, and it should be easier to fit the TV benchmarks without it. This should permit Tom to focus on support for the UI benchmark. The video-out code will probably have to be restructured to permit us to remove DLWS.

2) We will need differently configured Microkernels for each of the benchmarks (with and without calliope support, with varying sets of devices, etc.). We need to look at what Makefile changes are needed to make this as easy as possible.

We'd like to minimize the number of modules that have to be compiled separately for different configurations; how will trim_stack affect this?

At first glance it looks like the Makefile you're running is designed to work only on the SUN platform. I believe this is true of most of our Makefiles.

It seems to be trying to run "hostname" from /bin, and "hostid" from /usr/local/bin. On trex, these programs are found under:

/usr/ucb/hostname

/usr/ucb/hostid

The simple thing is probably to go back to a SPARC-10 machine and run it there.

the asnwer is no.

Sorry, mark, kept meaning to respond on this one. We are going
through a peak right now, which I think will drop off shortly once
Euterpe is finally behind us. Is there a logfile anywhere that shows
the usage? I know lisar has failed to get a license a few times, but
usage is peaky. If we are near the limint much of the time during the
day, we should do it, if we typically have a couple of spares and
only hit the limit occasionally I'd hold off. \$35K is a lot, and
the downside is really only the delta discount.

It appears the 6 pin power connector on the Euterpe module has 3 pins assigned to each of gnd and 3.3V. Since we need the option of plugging a 5V cronus module into the the same backplane slot we need 5V assigned on this connector even though it will not be hooked up on this module. Can we reassign to 2 pins each on gnd, 3.3V, and 5V?

I'm pretty sure Ron is using all 64 taps to implement his VSB filter but I don't know if it's a requirement. We're only using 32 for QAM because we don't have enough cycles on euterte to update 64 in real-time at the decimated rates we've chosen. Anyway, using only 32 is definitely a possibility but the performance we've measured is marginal, especially for longer echoes. This is a design choice that deserves a lot of discussion - we understand all of the tradeoffs so it really depends on what performance we need for the target application.

Wow. Given approx. 80000 Gards-visible nets, that's amazingly close to a switching probability of one-half. This is a *scary* microarchitecture for CMOS.

I wonder what fraction of those events are "useful"... (i.e. convey data that is used)

So here's a back-of-the-envelope calculation for the switching power:

Power = (Total Wire Cap.)*(Supply Voltage ^ 2)*(Switching Frequency) Total Wire Cap:
(from Euterpe...)

Average net length: .6mm

Number of nets: 80K

Capacitance/mm: 130fF (we use *some* M2)

(Cronus changes)

Average net length: .6mm * 1.5

I consider 1.5 to be a lower bound: while the wire pitch is 2.4x worse,
the number of wires is less and the CMOS gates take relatively less
space than their BiCMOS counterparts

Number of nets: 80K * .6

Again, .6 is probably a lower bound. Converting all differential
signals to single-ended at the top (hierarchical) level of euterpe.v
gives about .55, and these wires are most likely to be differential,
due to their length.

Capacitance/mm: 300fF

Supply Voltage: 5V

Switching Frequency: 400MHz * .25

.5 transition probability is one signal cycle every four clock cycles Switching

Power:

32.4 Watts

This is in addition to the clock power, which we've estimated at:
 $(50K \text{ flops}) * (100fF/\text{flop}) * (25V^2) * (400MHz) = 50 \text{ Watts}$ but the clock driver has substantially higher power due to its low skew and fast edge requirements. I think Bill's latest estimate was that to deliver 18A into the load required 28A total current, so I'll call 28/18 a 1.5x hit in power.

That would make our latest Cronus power estimate:

$$32.4 + (50) * (1.5) = 107W$$

not including custom blocks or the I/O.

So maybe we can hit our 150W target after all...

We are looking into it. Specifically, we are looking at 2 pins for
common 3V/5V gnd, 2 pins for 5V and 2 pins for 3V. A single contact
is rated for 30A, but that is not the same as working well at 30A.
Vijay has been assigned the task of analyzing how well 2 pins will
work. He has promised me that he will hav an answer today.

There appears to be something in the plot script which is causing
this. The values are fine in the actual schematics.
I am looking into fixing the plotting.

Sorry, I didn't mean to extend everyones week by re-living Thursday. Ha!?

Thanks David for informing me of the meeting conflict. I've rescheduled the Engineering conference room for Monday April 3rd at 10:00AM for the Pandora Euterpe PCB design review. Please let me know if there is another conflict.

New edits have come up:

- 1) Tooling holes are to be added.
- 2) New circuit for PLL pins.

The vias for diferential pairs have been moved. (possible .5 max length difference)

Thanks
-Pattie

Just to clarify, I have only supplied outline criteria and that having to do with the Euterpe and SDRAM areas. There are still features such as slots and hole to be placed outside the trace and component areas, and I am working on completing that design for early next week, but the layout we review Monday won't yet have those features in it. Does anyone have a problem with reviewing what we will have done by Monday (traces and components and pcb outline)?

Drew Wingard wrote (on Thu Mar 30):

Wow. Given approx. 80000 Gards-visible nets, that's amazingly close to a switching probability of one-half. This is a *scary* microarchitecture for CMOS.

Let's not get too scared just yet. There are far more "primitive" gates on the simulator than real gates, so we need to factor that in. I'd guess 2:1 for that.

I wonder what fraction of those events are "useful"... (i.e. convey data that is used)

At a wild guess, 20%.

So here's a back-of-the-envelope calculation for the switching power:

Power = (Total Wire Cap.)*(Supply Voltage ^ 2)*(Switching Frequency)

Total Wire Cap:

(from Euterpe...)

Average net length: .6mm

Number of nets: 80K

Capacitance/mm: 130fF (we use *some* M2)

(Cronus changes)

Average net length: .6mm * 1.5

I consider 1.5 to be a lower bound: while the wire pitch is 2.4x worse, the number of wires is less and the CMOS gates take relatively less space than their BiCMOS counterparts

Number of nets: 80K * .6

Again, .6 is probably a lower bound. Converting all differential signals to single-ended at the top (hierarchical) level of euterpe.v gives about .55, and these wires are most likely to be differential, due to their length.

Capacitance/mm: 300fF

Supply Voltage: 5V

Switching Frequency: 400MHz * .25

.5 transition probability is one signal cycle every four clock cycles

Switching Power:

32.4 Watts

This is in addition to the clock power, which we've estimated at:

(50K flops)*(100fF/flop)*(25V^2)*(400MHz) = 50 Watts

but the clock driver has substantially higher power due to its low skew and fast edge requirements. I think Bill's latest estimate was that to deliver 18A into the load required 28A total current, so I'll call 28/18 a 1.5x hit in power.

That would make our latest Cronus power estimate:

$$32.4 + (50) * (1.5) = 107W$$

not including custom blocks or the I/O.

So maybe we can hit our 150W target after all...

So given this data the inefficiency of having a majority of nodes switch without carrying useful data could well be eclipsed by the clock overhead.

Johnny,
 Thanks, I've locked down the layouts and releasebom'd them.

Tim,
 If you could do a getbom for the proteus snapshot for euterpe, then when that's done,
I can start up another round of lvs/drc checks on euterpe.

I'll start up the metals drc for mnemo and submit the lowers as well.

Thanks,
Dave

Hi Curtis,

I just thought we might chat about what all is going on in the 1394 market... not looking to hook ya for a consulting contract. Below is some information we have been sending out on our development kit.

We will be an OEM supplier for TI component PCI & Cardbus adapters later this year and early next year respectively. We are continuing to work on our embedded application chip design, but we are not prepared to discuss that project in detail yet.

cheers, g

=====
Section 1: The 1394 TK-01 Developer Toolkit =====

The 1394 Developer Toolkit provides the hardware and software tools required to implement IEEE 1394 communication. And remember, it's designed by Skipstone, the IEEE 1394 serial bus experts.

The 1394 Developer Toolkit contains:
-- 2 Skipstone PCI-01 Interface Cards
-- 2 powerful software development tools:
 -- 1394 Packet Injector
 -- 1394 Bus Analyzer
-- 1394 Bus Manager software
-- 1394 Application API, DLL and VxD
-- 1394 cable
-- Complete documentation

Also included are:
-- 4 months of free technical support
-- 6 months of free software upgrades

Note: TK-01 software may not be redistributed.

Technical Overview
=====

Skipstone PCI-01 Interface Card

an adapter card providing the interface between your computer's internal PCI bus and the external IEEE 1394 bus.

Packet Injector

a software tool allowing you to insert IEEE 1394 packets into the bus in either isochronous or asynchronous mode. The Packet Injector is used to simulate an IEEE 1394 data source to provide a controlled test environment for evaluation of your application.

1394 Bus Analyzer

a software tool allowing you to monitor IEEE 1394 packets being carried on the bus. The Bus Analyzer provides you visibility into what type of data is being sent and its content. Filters are provided to selectively limit what type of data you want captured and this data may be displayed or saved in memory for future analysis.

1394 Bus Manager

the Bus Manager provides overall configuration control of the serial bus in the form of cycle master assignment, isochronous channel ID assignment and error recovery.

API and DLL

the Development API is the programming interface to which your application and the Developer Toolkit's tools are written. The API is a collection of programming calls providing high-level support over bus communication that frees the application from worrying about the details of programming the low level interface to the IEEE 1394 bus. The Dynamic Link Library (DLL) is Windows ring 3 code implementing the API and providing an interface to the VxD (see next).

VxD

the virtual device driver for the Skipstone PCI-01 Interface Card. Written specifically for this card, the VxD is updated to reflect new releases or different designs of the IEEE 1394 interface thus making your application immune to hardware changes.

Computer Requirements

- fully IBM-compatible computer
- 486 processor at 66 MHz (faster if maximum bus rates are to be exercised)
- 1 PCI bus slot
- 8-meg RAM (16-meg preferred)
- 5-meg hard disk space
- Windows 3.1 or Windows for Workgroups 3.11, MS-DOS 6.22 or higher

TK-01 Developer Toolkit Release Schedule =====

The TK-01 Developer Toolkit is being released in stages to provide you the earliest possible access to IEEE 1394 technology. Be assured that purchasers of the initial releases are provided free updates to later releases of the TK-01 toolkit.

Release 1 - Now Shipping

- 2 Skipstone PCI-01 Interface Cards
- IEEE 1394 Application API and Virtual Device Driver for asynchronous data transfer
- File Transfer demo
- Source code example
- IEEE 1394 Cable
- Documentation
- 4 months of free technical support plus 6 months of free software upgrades

Release 2 - planned April 30, 1995

- Release 1 plus
- IEEE 1394 Application API, Virtual Device Driver and Resource Manager for isochronous data transfer with 1394 limited bus management
- IEEE 1394 Packet Injector and Bus Analyzer development tools
- Updated documentation

Release 3 - date to be determined

- Release 2 plus
- IEEE 1394 Full Bus Management
- Updated documentation

Additional 1H95 Skipstone products planned =====

PCI-10 Interface Card

a powerful upgrade of the current PCI-01 Interface Card. The PCI-10 contains a microprocessor to enhance performance.

TK-10 Developer's Toolkit

the TK-01 Developer Toolkit upgraded for use with the PCI-10 Interface Card.

TK-20 Embedded Application Toolkit

an enhanced Developer Toolkit specifically tailored for embedded applications.

Price List

=====

Part #	Product Name	Price
-----	-----	-----
TK-01	IEEE 1394 Developer Toolkit	\$7500
	-- 2 PCI-01 Interface Adapter Cards	
	-- IEEE 1394 Development Software	
	-- IEEE 1394 Cable	
	-- Toolkit Documentation	
	-- 4 months Technical Support	
	-- 6 months Software Upgrades	
PCI-01	Additional 1394/PCI Interface Adapter cards purchased with TK-01 Toolkit	\$ 495
PCI-01	1394/PCI Interface Adapter cards not purchased with TK-01 Toolkit (see Note 1)	\$ 695
PCI-10	Advanced 1394/PCI Interface Adapter - not yet available (see Note 2)	

Note 1: Price of PCI-01 interface adapter cards purchased without the Toolkit may be applied against price of Toolkit if the Toolkit is later purchased.

Note 2: PCI-10 interface adapter card is available only to purchasers of the Toolkit.

Note 3: There will be an additional \$60 fee for overseas delivery.

=====
Section 2: About IEEE 1394
=====

The IEEE 1394 high-speed serial bus promises to revolutionize the transport of digital data for computers and for professional and consumer electronics products. By providing an inexpensive non-proprietary high-speed method of interconnecting digital devices, a truly universal I/O connection has been created. Its scaleable architecture and flexible peer-to-peer topology makes IEEE 1394 ideal for connecting devices ranging from printers and hard drives to digital audio and video hardware with real time processing requirements for on-time multimedia.

IEEE 1394 is a standard, platform-independent solution. Its features represent an evolutionary improvement over current I/O interfaces and provides connectivity solutions for many markets. Legacy I/O bridges attach serial and parallel interfaces to 1394. ASCII SCSI-3 provides a migration path for parallel SCSI to move to IEEE 1394.

IEEE 1394 can interface with the higher layers of the new parallel port standard, IEEE 1284. Although IEEE 1294's 4 to 32 Mbps transfer rate is lower than that of 1394, 1284 finds application in printer connectivity since it is backward compatible with the existing Centronics parallel port.

IEEE 1394 devices of differing transport rates may be interconnected, allowing backward compatibility with devices having slower transport rates. This feature allows 100 Mbps devices purchased today to operate properly in future bus configurations involving 200 and

400 Mbps devices.

The IEEE 1394 serial bus is:

- a digital interface: there is no need to convert digital data into analog and tolerate a loss of data integrity
- physically small: the thin serial cable can replace larger and more expensive interfaces
- easy to use: there is no need for terminators, device IDs, or elaborate setup
- hot pluggable: users can add or remove 1394 devices with the bus active,
- inexpensive: priced for consumer products
- scalable architecture: may mix 100, 200, and 400 Mbps devices on one bus
- flexible topology: support of daisy chaining and branching for true peer-to-peer communication
- fast: even multimedia data can be guaranteed its bandwidth for just-in-time delivery

Broad markets for IEEE 1394 digital data transport include:

- computers
- audio, image, and video products for multimedia
- printer and scanner products for imaging
- hard disks, especially hard disk Raid arrays
- digital video camera, displays, and recorders

IEEE 1394 is currently defined by ANSI draft standard P1394. The IEEE Standards subgroup concerned with 1394 successfully closed its ballot on 1394 in December 1994 with formal 1394 approval anticipated in the second quarter of 1995.

=====
Section 3: The IEEE 1394 Trade Association =====

The IEEE 1394 Trade Association was formed in September 1994 to accelerate the market adoption of IEEE 1394. Of special importance are the technical working groups that focus on refining the IEEE 1394 specification. The Trade Association steering committee is currently composed of representatives from Adaptec, AMD, Apple, IBM, Lexmark, Microsoft, National Semiconductor, NCR, Philips, Seagate, Skipstone, Sony, TI, and Toshiba.

If you are interested in joining the Trade Association, contact Gary Hoffman, our CEO and chairperson of the Trade Association.
You may call 512-502-8464 or contact him directly at gary.hoffman@skipstone.com.

=====
Section 4: About Skipstone
=====

Skipstone was established in 1994 to become the central supplier of technology and products for the IEEE 1394 serial bus architecture.
Skipstone is focused totally on IEEE 1394 development and is committed to bringing IEEE 1394 to a dominant position in the computing, communications and entertainment markets.

I'm keeping a running list, I thought the power supply had been resolved after talking to both Woody and David... Thank you for the reminder.

I've checked the Engineering conference room and it is available tomorrow at 2:00. Let me know and this can be changed easily. We might think about having a review tomorrow 2:00 so everyone can think about it over the weekend. Then list the action items and schedule another review for say Tuesday? Even if the changes are mechanical... its worth a review.

Has David discussed holding off on the manufacturing until we are closer on Euterpe? Might be a good idea in case we discover ales and cures even on the Hestia Main board. We can have it ready for manufacturing with gerber files and all, ready to go at a momunts notice.

I think this is a good idea.

Johnny,
Thanks, I've locked down the layouts and releasebom'd them.

Tim,
If you could do a getbom for the proteus snapshot for euterpe, then when
that's done, I can start up another round of lvs/drc checks on euterpe.

I'll start up the metals drc for mnemo and submit the lowers as well.

Geert has a euterpe build going, so I don't want to mess with it till
he gives the OK. Also, this will pick up kurt's pin swap magic.
Are we sure all the problems are solved with the topt dumps on that
one?

We are looking into it. Specifically, we are looking at 2 pins for common 3V/5V gnd, 2 pins for 5V and 2 pins for 3V. A single contact is rated for 30A, but that is not the same as working well at 30A. Vijay has been assigned the task of analyzing how well 2 pins will work. He has promised me that he will hav an answer today.

David

I've checked the Engineering conference room and it is available tomorrow at 2:00. Let me know and this can be changed easily. We might think about having a review tomorrow 2:00 so everyone can think about it over the weekend. Then list the action items and schedule another review for say Tuesday? Even if the changes are mechanical... its worth a review.

Main thing is to keep ahead of Howard. I'd rather people had time to look at the plots/schematics before the meeting. (btw, please put lsr on the cc, she will be doing for pandora what wayne's doing for hestia). The monday morning time is fine with me.

Has David discussed holding off on the manufacturing until we are closer on Euterpe? Might be a good idea in case we discover ales and cures even on the Hestia Main board. We can have it ready for manufacturing with gerber files and all, ready to go at a momunts notice.

I have not discussed it with him, but it would make sense to hold off.
We won't have Euterpe for a long time yet, and we may find
changes we need to make as we complete the mechanicals and get to the
backplane.

I think this is a good idea.

I will put this on the agenda for my Pandora meeting Friday and let
you know what the outcome is.

Oh okay. No problem. I can still run stuff on mnemo to keep the machines busy.

I've done a bit more testing and actually confirmed the change I made to topt was the correct one. I've not heard about any other core dumps from the new port properties. TVo has found a bug when he tried to force an instance to a power level where topt chose a non-buffered version instead of a buffered version which only resulted in a timing violation, no core dump.
I'll fix that tomorrow.

Thanks,
Dave

we are about to introduce a change to the pad corner test devices which will reflect a change at the toplevel. padtr will essentially go away as a schematic instantiation and padbr will lose one pin (bjtle_v) which will now be tied to vsse (ie remove from the verilog etc.)

how do we handle this change.

it is now ready to checkin the schematics but it will break the toplevel if we do.

Are we talking about mnemo or euterpe?

We are planning another snapshot update this weekend to pick up some routing rule changes. We should co-ordinate with that. I assume these changes will require baseplate regeneration.

I cannot figure out why it says this :

```
# pim2pif Version 0.2.50 Thu Mar 30 10:33:34 PST 1995
# /n/ghidra/s3/geert/euterpe/tools/bin/pim2pif.ex
gards/geert_euterpe-iter.pim -ecl -logFile guards/geert_euterpe-iter.pim.warn -noHole -xoff
\set 2 -yoffset 2
FATAL: Couldn't create the .pif file
:gards/geert_euterpe-iter.pim.pif.52: for writing
FATAL: Errors encountered in .pim section 52
FATAL: Errors occurred on some section(s) of the .pim file
```

This is in /n/ghidra/s3/geert/euterpe/verilog/bsrc/gards

The pim file is geert_euterpe-iter.pim

This means that fopen() returned an error code. Typically this means that there is no space left on the disk. But there seems to be room (unless pim2pif cleaned up a lot of stuff when it exited). I'll poke around, but you could run it again and keep an eye on disk space with (df .) to see if it hits 100%.

We should not have to regenerate the baseplate as long as the cell origin remains the same . The baseplate lower layers will be different though once that cell got updated in \$(CHIPROOT)/proteus/compass/layouts .

Subject: Update snapshot proteus/misc?

Hi, Tim -

I would really like to have the pin permutation on XBOR & XCNAND gates available for this weekend's top-level route. It looks like the only missing piece that remains is to update proteus/misc/emerge.tab. In the event that we're unable to get a top-level getbom & build done in the proteus snapshot before the top-level route, would it be permissible to update that one file in the *proteus snapshot*?

I checked with Dave Van't Hof; he has confirmed that his topt fix related to the pin properties is reliable, and the relevant changes to the GPLACE incantation are in place in the euterpe snapshot, so I think the stage is set if we can get that one file brought up to date. Is this acceptable?

- Kurt

Subject: Plots for Euterpe PCB Review

Copies of the current layout state are being distributed for your review.
The meeting is still scheduled for Monday 10:00 in the Engineering conference Room. There are still many edits required to complete the board. Here's the list so far:

Netlist edits:
New circuit for PLL pins.
Add 5v to the Power Connector.
Add ground net to connector tabs (flange).

Verification:
The vias for differential pairs have been moved. (possible .5 max length difference)
Do we need/want test points?
Has logo been approved?

Mechanical:
>From tbe@microunity.com Thu Mar 30 16:08:52 1995
> Just to clarify, I have only supplied outline criteria and that having to
> do with the Euterpe and SDRAM areas. There are still features such as
> slots and hole to be placed outside the trace and component areas, and I am
> working on completing that design for early next week, but the layout we
> review Monday won't yet have those features in it. Does anyone have a
> problem with reviewing what we will have done by Monday (traces and
> components and pcb outline)?

Layout issues:
Add ground plane around corner of tab.
Clear tab of solder mask.
Rename components - Back annotate.
Drawing dimensions, detail for cutout
Round up special notes for drawings, Fab and Assy
Create Gerbers, drill, ncrouter

**Depending on the edits and changes listed above, Tuesday evening would be the earliest this board can be archived for manufacturing.
